Abstract

This article considers the historical legacy of European dominance over individuals from racialized groups. It discusses the social construction of race as it relates to culture and the subsequent oppression of individuals from racialized groups. Practice frameworks for working with individuals from racialized groups are discussed and implications for social work practice are also included.

Introduction

Whilst racially sensitive social work practice has been used historically when teaching about practice with specific racial and ethnic groups (Devore and Schlesinger, 1981/1999), it has not maintained its currency, largely because it did not address issues of systemic racism and oppression. In this article, we consider the historical legacy of European dominance over individuals from racialized ethnic groups, their subsequent oppression, and consider frameworks for practice with these groups. It begins with a discussion of the social construction of race as it relates to culture, and then practice frameworks for working with individuals from racialized groups. It concludes with a discussion of implications for social work practice.

Race as a Social Construct

Understanding the social meanings attached to the word 'race' encourages an analysis of the social processes that give meaning to the word 'race.' The concept of racialization focuses on the process by which 'race' becomes meaningful in the context of unequal power relations rather than on 'race' itself. Racialization supersedes the 'race relations' paradigm in both the United Kingdom and the United States because it looks at how certain groups have come to be defined as groups of stratified 'races' and the various factors involved in the institutionalization of racism (Garner, 2010). "[R]acism exists throughout the globe … and provides a basis for social exclusion on the basis of race" (Dominelli, 1997: p. 7). Such exclusion is considered normal when dominant groups consider those who are different as the 'other.' Othering is the process of treating difference as deviant or pathological and therefore undesirable (Dominelli, 2003: p. 17). Othering reproduces privileges those that are deemed to belong, and disadvantages those considered outsiders.

Historically, interactions between those of European decent and individuals from racialized groups of people were dichotomous in nature with one group being the oppressor (European) and the other group being the oppressed. According to Vickers (2002), the term racialized refers to "the political and ideological processes by which populations are linked to physical characteristics" (p. 190) and socially constructed as racially distinct, primarily based on a manifestation of unequal power between groups (Baum et al., 2001).

The division between these two groups depicts one of the deepest and most pervasive histories relating to 'race' relations and racism. The concept of 'race' has been deeply involved in constructing and rationalizing imbalanced social relations since it was introduced in the seventeenth century (Baum et al., 2001). The primary purpose of this construction was to separate the European or dominant group from other groups of people and exclusion was the guiding principle for social order (Deters, 1997; Christian, 2000), as evidenced, for example, by rules about citizenship, immigration laws, and apartheid (Gillem et al., 2001). This view has also evolved out of a historical need to create a hierarchy that would maintain the status quo of European supremacy, dominance, and privilege.

Some social scientists view race as a social construct (Dominelli, 1997; Better, 2008; Kirton, 2001; Parker and Song, 2001) with harmful effects, while recognizing that racialized identities can be an important mobilizing force for those struggling against discrimination and disadvantage (Parker and Song, 2001). According to Baum et al. (2001), understanding race in terms of racialization avoids any reification of racial difference because it emphasizes the historically changing and politically contingent nature of the process of racialization. Therefore, according to the social constructionist view, race is a product, not a cause of racism (Kobayashi and Johnson, 2007).

Culture

According to Better (2008), a social construct is a culturally determined idea. Therefore, race must be understood within the context of culture. However, culture is not static and cannot be viewed as being uniformly distributed or having a uniform impact on all members (Korbin, 2002). Culture is "a complex whole that includes knowledge, values, beliefs and other capabilities and habits of people" (McGibbon and Etowa, 2009: p. 65).

Thus, a fixed definition reduces culture to stable groups of characteristics (Korbin, 2002) and encourages the perpetuation of stereotypes that do not recognize the ongoing changes that people and societies undergo (Mederos and Woldeguiorguis, 2003). Moreover, a fluid definition of culture recognizes change and individual differences while recognizing the lasting impact of certain experiences (Mederos and Woldeguiorguis,

2003; Yee and Dumbrill, 2003) and set the stage for more responsive service delivery (Mederos and Woldeguiorguis, 2003).

While maintaining the idea that culture is not static, it is necessary, "to unpack culture to understand how it works in all of its complexity" (Korbin, 2002: p. 638). The postmodernist understanding of culture is that all cultural identities are socially and historically constructed and, therefore, changeable in response to different internal and external contingencies (Williams, 2006). Accordingly, postmodern cultural 'competence' involves exploring the collection of identities and experiences that produce continually evolving, unique cultural experiences for clients (Dean, 2001).

A scan of the available research that discusses the dynamics of 'race,' culture, and ethnicity revealed terms such as cultural sensitivity, cross-cultural competence, cross-cultural expertise, cross-cultural effectiveness, cultural responsiveness, cultural awareness, culturally skilled, cultural competence, cultural safety, culturally relevant, and multicultural competence. Each of these terms include the term 'culture' which alludes to the idea that one can strive to become effective working with various cultures as opposed to analyzing the social processes that contribute to the racialization of groups of people.

Whaley (2008) found that cultural sensitivity and cultural competence were among the most popular terms used in the existing body of literature. Moreover, he found that the majority of literature encompassed cultural sensitivity while a smaller portion of the literature made reference to cultural competence. Although these two terms were noted to be the most popular in the existing body of literature, cultural sensitivity seemed to be more common in the existing body of literature (Whaley, 2008).

However, a focus on cultural competence and cultural sensitivity fails to recognize, and therefore does not challenge institutional racism (Dominelli, 1997).

Cultural Competence and Cultural Sensitivity

Modernist cultural competence has been a construct on which programs related to diversity have been based. Cultural competence is defined as "a set of congruent behaviors, attitudes, policies, and structures that come together in a system or agency or among professionals and enables the system, agency, or professionals to work effectively in cross-cultural situations" (Cross et al., 1989: p. 7). Cultural competence can be conceptualized as consisting of components such as cultural awareness, the affective dimension; cultural sensitivity, the attitudinal dimension; cultural knowledge, the cognitive dimension; and cultural skills, behavioral dimension (Rew et al., 2003).

Cultural competence may not be an appropriate construct because competence in a specific cultural group is likely not transferable between individuals, families, and communities (McGibbon and Etowa, 2009). The concept of cultural competence denotes working with cultural groups other than one's own (Korbin, 2002) and "the ability to transform knowledge and cultural awareness into health and/or psychosocial interventions that support and sustain healthy client-system functioning within the appropriate cultural context" (McPhatter, 1997: p. 261).

Moreover, some researchers (Pon, 2009; Sakamoto, 2007) feel it promotes an out-dated view of culture and is a form of racism. According to Pon (2009), cultural competence is similar to the processes involved in racism by means of "otherizing non-whites and by deploying modernist and absolutist views of culture to promote racialized and stereotypical views of cultural groups without ever having to use racialist language" (p. 64).

As an attempt to encourage cultural sensitivity, the perceived cultural differences may promote stereotypes and reinforce the concept of 'others' while perpetuating the idea that certain behaviors should be controlled and adjusted to resemble the norms of the dominant group (McGibbon and Etowa, 2009). For example, this approach assumes that cultural groups have stable identities, creating harmful stereotypes such as "Africans believe this … Mexicans believe that …" (McGibbon and Etowa, 2009: p. 76).

Consequently, these groups continue to be denied the realities of systemic racism, discrimination as well as other forms of social disparities and blamed for their difficulties (McGibbon and Etowa, 2009). Additionally, Dean (2001) views the concept of cultural competence as flawed. She argues that cultural competence assigns membership, into cultural categories, by particular aspects of identity such as race or ethnicity, which are viewed as fixed and sustained over time.

One of the challenges of using a cultural competence model is that it operates at an individual level, by applying specific techniques and skills based on a person's perceived knowledge about a particular culture. In a diverse society, people choose between various cultural options offered by a variety of cultural traditions. This approach does not capture the diverse, fluid, and complex nature of culture. Moreover, it may attempt to predict the beliefs and behaviors of those with racialized identities based on what is known about a person's 'race' or culture.

Since it is not possible to predict how a person from a particular culture self-identifies, a person's group membership cannot be assumed to indicate their culture. Moreover, stagnant definitions of culture fail to effectively address diversity, within membership to a cultural group, leaving minimal space for cultural change (Dean, 2001). Consequently, such an approach may inadvertently place blame on a person's culture. It may also emphasize cultural differences, which can obscure structural power imbalances, on an institutional level.

Cultural competence does not reach far enough in addressing institutionalized oppressions. It can leave those working from this approach, unequipped to deal with institutional racism and oppression, where it permeates, on structural and global levels. Moreover, it only reifies existing racial categories rather than deconstructing systemic factors that contribute to racism, discrimination, and oppression. Despite the widespread application of cultural competence, to promote organizational practices to meet the needs of diverse populations, it remains a vaguely defined goal, due to the elusive nature of its central construct, which is culture. Additionally, a failure of the cultural competency models is that they do not take into account the impact of colonization and the enduring legacy of oppression and domination, especially that imposed by the North on the South (Dominelli, 1997; Bernard and Moriah, 2007; Carniol, 2000; Dalrymple and Burke, 1995; Christensen, 1991; Fong and Gibbs, 1995).

A reliance on cultural competency frameworks can become what Dominelli (2003) calls a 'tool kit' approach to social work.

Social Work Ethics

Despite the elusive nature of culture, and the problematic of cultural competency models, ethical standards for social work practice in North America are based on both cultural competence and cultural sensitivity. Moreover, providing culturally competent practice has been at the core of ethical social work practice (Jackson and Samuels, 2011). According to the National Association of Social Workers (NASW),

> Culturally competent services are needed beyond race and ethnicity. Culturally competent social workers are also better able to address issues of gender and help persons with disabilities, older adults, gays, lesbians, bisexuals, and transgender people. A working knowledge of these groups' cultures and values helps social workers tailor care so it is effective and appropriate for their clients' needs. (NASW, 2008: p. 8)

Therefore, social workers are ethically required to understand cultural competence and social diversity. More specifically, "social workers should obtain education about and seek to understand the nature of social diversity and oppression with respect to race, ethnicity, national origin, color, sex, sexual orientation, gender identity or expression, age, marital status, political belief, religion, immigration status, and mental or physical disability" (NASW, 2008: p. 8).

Likewise, according to the Canadian Association of Social Workers (CASW)

> Social workers do not discriminate against any person on the basis of age, abilities, ethnic background, gender, language, marital status, national ancestry, political affiliation, race, religion, sexual orientation, or socio-economic status. (CASW, 2005: p. 4)

Specifically, social workers are required to demonstrate cultural awareness and sensitivity by striving to understand culture and its function in human behavior and society, recognizing the strengths that exist in all cultures, acknowledging the diversity within and among individuals, communities, and cultures. They should acknowledge and respect the impact that their own heritage, values, beliefs, and preferences can have on their practice and on clients whose background and values may be different from their own, as well as those perceived as similar. They should seek a working knowledge and understanding of a client's racial and cultural affiliations, identities, values, beliefs, and customs. A critical exploration of culture demands that social workers also examine the intersections of oppression, and to be aware of the diversity of experiences and realities within groups as well (Dominelli, 2003; Christensen, 1991; Zamparo et al., 2000)

Lastly, where possible, social workers should provide or secure social work services in the language chosen by the client (CASW, 2005: p. 4). Acknowledging the historical processes that have contributed to socially constructed ideas about race is crucial to attempt to gain an understanding of the oppression individuals from racialized groups faced historically and continue to experience presently.

Oppression

As outlined at the beginning of this article, oppression was historically based on coercive laws and rules to preserve the dominant European groups. According to Mullaly (2002), oppression is determined by a person being blocked from opportunities to self-development, being excluded from full participation in society, not having certain rights that the dominant group takes for granted, or being assigned a second-class citizenship. People with racialized identities have been discriminated against historically and are more likely to be oppressed on social, institutional, systemic levels and can result in internalized oppression (Mullaly, 2002). Oppression is complex, multidimensional, and fluid (Dominelli, 2003: p. 9) and is evident in social relations. Dominelli (2003) states that those in the dominant group deny and block access and agency to those in the target group.

Socially, members from racialized groups may be categorized and mistreated by virtue of their racialized identities. Once a social definition is constructed, various social practices and psychological responses contribute to institutional racism. Institutional racism "exists when the established policies and practices of a particular organization reflect and produce differential treatment towards, and outcomes for, various groups" (James et al., 2010: p. 89).

On an institutional level, this can be seen through laws, customs, and practices that exist to perpetuate inequities based on a person's racialized identity. Because individuals from racialized groups are excluded from the dominant privileged social positions and included in the subordinate group they may experience exploitation, marginalization, powerlessness, cultural imperialism, and violence. The processes involved in the institutionalization of racism illustrate how oppression is expressed and reproduced systemically by the actions of institutions and individuals working within these institutions.

Systemically, exploitation is realized through a structural relationship between the 'haves' and 'have not' groups. Also social rules about what work is, hierarchies in agencies, differences in wages all operate through a systematic process to produce and reproduce relations of power and inequality. This can be seen through the expectations that members from racialized groups will carry out menial labor tasks while management positions are held by members of the dominant groups. Accordingly, members from racialized groups are likely to be exploited and subjected to further marginalization (Young, 1990).

Marginalization primarily affects individuals from racialized groups who are, by virtue of social constructions, "confined to the margins of society because the labour market cannot or will not accommodate them" (Young, 1990: p. 43). These situations can contribute to these individuals feeling powerless. Young (1990) indicated that powerlessness affects primarily nonprofessional workers, but also individuals from racialized groups and is based on the social division of labor.

In this sense, the power and respect that accompany the privileged status of being professional also involve racism whereby, individuals from racialized groups who are professionals must continuously prove they deserve respect and that they belong (Young, 1990; Dominelli, 1997; Better, 2008; Bernard, 2006).

According to Young (1990), cultural imperialism is when the dominant group universalizes their experience and culture and uses them as the norm by projecting their experience and culture as representative of all humanity. The dominant group reinforces their position by measuring other groups according to dominant norms, to construct individuals from racialized groups as inferior and deviant (Young, 1990; Este, 1999).

Most oppressed groups suffer systematic violence simply because they are subordinate in the social pecking order (Young, 1990). This violence is not always physical. It can be manifested through harassment, ridicule, and intimidation, which serves the purpose of stigmatizing individuals belonging to subordinate groups.

Experiencing the combined effects of social, institutional systemic oppression can have a damaging impact on the psyche of individuals from racialized groups. Two psychological conditions brought about by oppression are a sense of inferiority and internalized oppression (Mullaly, 2002). A sense of inferiority denotes an acceptance of a second-class citizenship status in society by a member of an oppressed group and a belief that he or she and all members of that group are inferior to the dominant group (Mullaly, 2002). Internalized oppression not only includes the belief that one's self and one's social group are inferior, but also encompasses the behaviors that are self-harming and contribute to one's own oppression (Mullaly, 2002).

Accordingly, oppression occurs through the systemic constraints on members of racialized groups and "is more effective in achieving its apparent function of maintaining the privileged position of the dominant group when both victims and perpetrators are unaware of the dynamics of oppression" (Mullaly, 2002: p. 40). Subsequently, this lack of awareness is critical in worker–client interactions for both the worker as well as individuals with racialized identities.

Existing research highlights a variety of approaches aimed at increasing awareness in order to address oppressive policies, practices, and interactions between people. These approaches have centered on static ideas of culture that do not take into account that cultural identities are socially and historically constructed as well as the subsequent oppression of individuals from racialized groups.

Implications for Social Work Practice

Social workers practice in diverse societies increases the likelihood of working with members from racialized groups. According to Fook's approach to social work, as cited in Payne (2005), social work "concentrates on rethinking ideas about practice through knowledge, power, discourse, language and narrative, and identity and difference" (p. 243). Fook proposes a critical reflective approach to practice which challenges domination in external structures, social relations, and personal constructions and recognizes multiple and diverse constructions (Payne, 2005).

Social workers should be aware of the historical legacy of race relations in order to explore the social construction of race as it relates to oppression of individuals with racialized identities. Graham et al. (2010) found that alternative perspectives of the helping relationship need to be considered to allow for service delivery that meets the unique needs of individuals. To recognize the need for specific consideration of the cultural values and issues for those from racialized groups, perspectives need to be developed beyond the frontline level to more inclusive service delivery based on a structural analysis (Graham et al., 2010).

According to Graham et al. (2010), "social services in North America and beyond need to incorporate these ideals into practice and policy by rejecting cultural assumptions and stereotypes and realizing that different cultures face adversity in different ways" (p. 345). Their findings confirm that there is no all-inclusive way to work with those with racialized identities and agency policies as well as practices needed to evolve in dynamic ways and meet the unique needs of individuals. Similarly, Fook (1993, 2002), Payne (2005), Dominelli (1997, 2003), and Hugman (2010) call for a reimagining and rethinking of social work that addresses racism and oppression at each level; the individual, institutional, and cultural. Furthermore, such practices are envisioned as leading to a more socially just world.

Social service agencies and their workers working with individuals from racialized groups need to be aware of the historical processes that were legally sanctioned and contributed to the social construction of race. Because race as a social construction is a product, not a cause of racism (Kobayashi and Johnson, 2007), the exclusionary measures that were once overt are now subtler, but still seek to preserve the privileges of the dominant group. Social workers need to address these dynamics related to racism, discrimination, and oppression at micro-, mezzo-, and macrolevels to begin to redress the historical and present-day influences of discrimination and oppression.

On a microlevel, social workers must first begin to understand how the social construction of race and its perpetuation of oppression affect members from racialized groups. They must also recognize the reality of racism and be willing to challenge both the theorists' and the therapists' world with regard to the presence of racism (Deters, 1997). Successfully and sensitively working with people from racialized groups requires that the social worker has explored and continues to explore how she or he has internalized rules of racial categorization and any of the accompanying stereotypes. They must ask themselves questions such as what are my own assumptions about groups with racialized identities? What are my own internalized rules? How do my own internalized rules affect the way I work with my clients? How does my own racial identity or privilege impact the therapeutic relationship? This personal work by social workers is critical to creating a non-pathologizing environment (Dominelli, 1997; Christensen, 1991; Deters, 1997).

Furthermore, social workers must challenge socially constructed ideas about clients from racialized groups in order to encourage clients' stories about the oppression they have faced. As such, social workers must seek out, learn, and encourage the further development of theories that reflect the developmental

process of more than socially constructed ideas of racialized groups.

At a mezzo-level, social workers should consider focusing their intervention activities on the local institutions and organizations to which individuals from racialized groups belong. This will assist in the education and sensitization of agencies and agencies, personnel about the needs of individuals from racialized groups. For example, Ben Carniol (1995 quoting Moreau and Leonard) highlights the various empowerment practices that social workers engage in, within their practice, as well as in their communities. Similarly, Bernard (2006) shares stories from Black social workers in their fight for change in policy and practice in Nova Scotia. Specifically, a social worker can advocate for changes in the organizational policies and procedures for more effective responses to those identified needs. Dhooper (2003) suggests this can be accomplished through communicating and negotiating effectively with local institutions and organizations by involving communities of racialized groups to bring about significant institutional changes.

Finally on a macrolevel, social workers need to study their society to reveal the ways that forms of oppression can create problems out of socially constructed differences. This will allow social workers to build better communities with more trustworthy services and institutions, as well as better relationships and understanding with clients (Dean, 2001). According to Dhooper (2003), racism continues to divide North America and individuals with racialized identities still often find themselves subject to marginalization, discriminatory, as well as oppressive practices. Therefore, social workers should participate in policy-level discussions and search for solutions aimed at challenging social constructions that contribute to unjust racial hierarchies and safeguarding the interests of individuals with racialized identities.

Conclusion

Since 'race' is not fixed by nature, understanding the process of racialization brings the historical, social, and political processes to the forefront of the institutionalization of racism. Without an understanding of the concept of racialization, these processes can continue to make 'race' the constructed idea that resources are allocated, policies as well as programs are developed, and training is delivered. Is it not time to move beyond this notion of ethnic sensitive and culturally competent practice? As Hugman (2010: p. 157) asserts, "… cultural competence is not just about acquiring a set of skills, knowledge and values, but it is also about rethinking and reimagining social work. Rethinking and reimagining social work *must* embrace an anti-racist and anti-oppressive perspective to challenge structural inequality at its core," a vision outlined by Dominelli in her first edition of *Anti-Racist Social Work* and repeated in the 1997 second edition. Social work in the twenty-first century is well-positioned to be the "bridge between social work in a racist society and social work in a non-racist one" (Dominelli, 1997: p. 167), but to get there we must move beyond notions of ethnic sensitivity and cultural competence.

Abstract

This article describes the history of the concept of 'the social' as a substantivated adjective. Despite the growing use of the terms 'society' and 'social' in the eighteenth and nineteenth century, it is only at the beginning of the twentieth century that 'the social' started being used as an independent concept. In its simplest and most general meaning, 'the social' is the ensemble of phenomena involving a relation between human beings, and thus distinct from the individual and the natural. Emile Durkheim and Marcel Mauss used the expression in this sense. In the 1950s, Hannah Arendt gave a more limited meaning to the expression: she spoke of 'the rise of the social' to describe and criticize the development of modern industrialized societies; in these societies, economic activities (the production and consumption of goods) have become the primary concern of individuals, and the distribution of benefits the central activity of governments, resulting in a loss of political freedom. In the last decades of the twentieth century, the importance of the concept of 'the social' has steadily grown, thereby becoming one of the fundamental notions of the social sciences, central to many social theorists. 'The social' has thereby acquired a meaning of its own, independent of 'society': a more abstract term applicable to the macrolevel, as well as to the microlevel and with less connotations of homogeneity and boundedness, it is even often described, instead of 'society,' as the proper object of the social sciences and social philosophy.

As a concept, 'the social' results from the substantivation of the corresponding adjective. Consequently, the history of its usage is closely related to the emergence and diffusion of the adjective 'social' and of the noun 'society.' The oldest roots of 'society' and 'social' are the Latin *socius*, a companion, which ultimately derives from *sequi*, to follow (Latour, 2005: 6). In current usage 'society' stands primarily for (1) a voluntary association of individuals with common goals; (2) more commonly and more abstractly, the most general context of human interrelations – a framework with identifiable boundaries within which human beings interact with a higher degree of intensity, and in which these interactions typically solidify in habitual practices, enduring representations, and institutions.

'Society' and 'Social' in the Eighteenth Century

Historically speaking, the first of these two meanings is older, but the second one has become more prevalent since the emergence of the social sciences. In the mid- to late eighteenth century, both meanings were equally present: 'society' shifted in meaning between 'partnership for a particular purpose' or 'companionship,' and "the basic form of collective human existence" (Baker, 2001: 86, 95). Quantitatively, the use of the word 'society' also grew, arguably in a reflection of two phenomena (Honneth, 2000: 14): first, the increasing visibility and role of associations, clubs, and salons; second, the development of geographic mobility and long-distance interrelations, especially of the commercial type. At the same time, society, in particular for the political philosophers of the time, was as much a future goal as it was a present reality. One aspect of the project of the thinkers of the social contract was, for instance, to transform the arbitrary communities inherited from the past into conscious associations of individuals founded on an explicit agreement, thereby turning 'society' in the second sense into a 'society' in the first sense (Sewell, 2005: 322, 323). A new entity that Thomas Hobbes called 'commonwealth' and John Locke 'civil society' would thus be brought into existence. In this line of reasoning, social relations are implicitly assumed to be a malleable, transformable stuff that could be shaped with relative ease by the action of governments (Terrier, 2011: xxiv, xxv; Nisbet, 1976: 241–251). This conception, however, was resisted by other equally influential political philosophers, such as Montesquieu, David Hume, or Adam Smith, who envisaged society as the spontaneous outcome of human interactions in specific historical and geographic contexts (Sebastiani, 2013). While politics could give some orientation to social developments, it could not completely redefine society in the second sense, which was perceived by these authors as a historical, not an artificial entity.

These debates on 'society' during the eighteenth century and the growing use of the term were accompanied by a parallel rise of the adjective 'social.' The quantitative diffusion of this adjective in France is well documented (Mintzker, 2008). While 'society' and 'sociable' were of common usage already in the seventeenth century, 'social' became prevalent only in the following one. Its original meaning was close to that of sociable, especially in expressions such as 'social virtues' (Mintzker, 2008: 505): it was used to qualify a person as polite, respectful, and well capable of human interaction. Later, 'social' was more and more used as the adjective of society in the second sense, with the meaning of 'pertaining to an organized group of human beings.' It is in this sense that Jean-Jacques Rousseau used the term in his *Social Contract* (1761), the first book to bear the adjective in its title, closely followed by Baron d'Holbach and his *Social System* (1771). 'Social science' and 'sociology' were late eighteenth-century coinages – both by Emmanuel Sieyès, a French revolutionary who insisted that the major task of the French National Assembly in 1789 was the creation of a politically and socially unified nation (Sewell, 1994; Guilhaumou, 2006). These expressions were popularized during the nineteenth century by Saint-Simon, Auguste Comte, and John Stuart Mill (Baker, 1964, 1989).

'Society' and 'Social' in Early Social Science

During the nineteenth century, two developments were of particular importance. To begin with, due to the growing influence of the labor movement, 'social' acquired a further meaning, namely 'concerning the poorer classes of society' as well as 'concerning the relationship between workers and employers.' Expressions such as 'the social problem' (used by Mill in 1851 in his *Autobiography*, cf Burchfield, 1986: 315) or 'the social question' (documented in French as early as 1834 – Rey, 1992: 1958) can serve here as examples. Second, by the end of the nineteenth century, the definition of 'society' as a large, bounded, and organized group of human beings became the default one. This was the result of the diffusion of the discourse and practice of the social sciences. Against the traditional emphasis of political philosophers on ideas, consciousness, and will, the social sciences were organized around the assumption of a 'thickness' and 'opaqueness' of human interrelations: they thematized the existence of collective habits and representations determined by historical contexts which could not be changed at will. The history of the social sciences is marked by a debate on the correct identification of the most important contexts to consider when trying to explain the various features of collective life. During the nineteenth century, naturalistic approaches were especially influential: many authors highlighted climate or race as major determinants of human behavior. Starting around 1890, this naturalism was increasingly challenged by classical sociology and social anthropology (Turner, 2006: 135). A common conviction of the 'Founding Fathers' of the social sciences (among others Emile Durkheim, Georg Simmel, Franz Boas, Max Weber, Marcel Mauss) was that, in Durkheim's formulation (1895), social facts should be explained by social facts, as opposed to natural ones. On the other hand, these authors were in clear disagreement concerning the nature of their object. Durkheim took it to be 'society' itself, an entity with distinct boundaries and a clear internal unity. By contrast, Weber emphasized 'social action' and Simmel emphasized 'interaction' (*Wechselwirkung*).

It is precisely here that the history of 'the social' as a substantive really starts. Before this time 'the social' either was unavailable as a noun (for instance, in Germany or in France, cf Rey, 1992: 1958) or it had, in English, the limited, concrete meaning of a 'small gathering,' a 'sociable meeting' (Poovey, 2002: 127). Without turning it into a major concept, Emile Durkheim and Marcel Mauss both made use of 'social' as a substantive, especially in contrast to other realms such as 'the psychological' or 'the individual' (Mauss, 1969b: 154; Durkheim, 1975: 25; Mauss, 2004: 138). They used the term to refer to the ensemble of phenomena displaying the characteristics of social facts. In the definition of Durkheim, the criterion of a social fact is that it exerts an external constraint on individual thought and action, as in the case of habitual practices, moral obligations, or legal norms. Mauss had a broader understanding of the social. He relativized the Durkheimian dichotomy of the individual and the social and tried to show how all collective representations and rules are reinterpreted by individuals, and therefore progressively transformed by them. He also offered a theory of the way in which individuals, when they are associated in political movements, can collectively modify the shape of the society (Mauss, 2013). Mauss defined the social as "that which is common only to the men who live in a clearly defined and organized single society," and contrasted it to the 'psychological in its pure form' (*le psychique pur*), which is common to all human beings (Mauss, 1969a: 227).

In Germany, in the same years, 'social' also started being used as a substantive by some authors. Even though 'the social' was not central in their work, both Weber and Schmitt used this expression and proposed explicit definitions. In his 1905 essay on "objectivity in the social sciences," Weber mentioned "the relationships among persons" as the vague but characteristic focus of a particular perspective on human beings which he called the "standpoint of the 'social'" (*Gesichtspunkt des Sozialen*) (Weber, 2011: 67, translation modified). In his *Concept of the Political*, Schmitt (1996a) argued that the enmity between groups is at the core of all political phenomena. 'The political' in this sense needed to be distinguished from 'the social' (*das Gesellschaftliche*), which is the realm of interaction between human beings for specific purposes (Schmitt, 1996b: 79), as opposed to the overarching, more fundamental purpose of group survival and the defense of collective identity.

Especially relevant to a history of the concept of the social are the skeptical views of both Simmel and Weber on the notion of 'society.' The two authors warned against the danger of hypostasizing society, i.e., of envisaging it as an actor in its own right, distinct from its members. When sociologists view society as a person (a tendency which was not absent from the work of Durkheim), they tend to project upon it all the various characteristics of an individual human being, such as a hierarchical form of organization, a strong internal homogeneity, and clear-cut boundaries. Even though societies, according to Simmel and Weber, may well take such a form in given circumstances, these elements should not be considered as necessary features of social life. To avoid these connotations of homogeneity and boundedness, both authors advised to speak of 'socialization' (*Vergesellschaftung*) as a process, as opposed to 'society' as an entity. This skeptical judgment on the concept of society became a recurrent theme in twentieth-century social science. The social scientists who introduced, during the twentieth century, new concepts that should serve as alternatives to 'society' (including 'the social') often found inspiration in their early criticism.

After World War II

In the decades following World War II, the idea of society as a bounded, tightly integrated totality became prominent, especially in American sociology (cf Urry, 2000: 11). Correspondingly, there was little conceptual space for a theorization of 'the social' as broader than, and thus distinct from, 'society.' Nevertheless, the concept of 'the social' remained in use, with markedly different meanings, in particular among those who were critical of the then dominant sociological theories.

An especially prominent example of a systematic use of 'the social' as an independent concept is Hannah Arendt (*The Human Condition*, 1998/1958). Her notion of the social was very idiosyncratic and can be only understood against the background of her entire political philosophy. For her, 'the social' is

that which pertains to the "life process when it has been channeled into the public realm" (Arendt, 1998: 45). Following Aristotle, she made a distinction between the public space of the *agora* and the private space of the *oikos* (household), in which economic activities take place. According to her, in Greek times the reproduction of material life was a private concern with little political relevance: "whatever was 'economic,' related to the life of the individual and the survival of the species, was a nonpolitical, household affair by definition" (Arendt, 1998: 29). 'The social' appeared during modernity as a consequence of a blurring of the distinction between the public and the private. With the rise of industrial society and its social problems, the question of material survival became a topic of collective interest. What was previously a private concern and a private endeavor was increasingly made public, thus creating a "curiously hybrid realm where private interests assume public significance" (Arendt, 1998: 35). This transformation, for Arendt, had disastrous consequences. While human beings possess different visions of freedom and the good, they all have similar physiological needs. When the political question of good government is replaced with the social question of the fulfillment of needs, speech, especially political dialogue, is no longer required. Governments can treat individuals as if they were identical and dispense with any serious democratic consultation of citizens. Politics turns into a mere allocation of resources, an administration of things. The public sphere where diverse individuals can confront their own visions of the good vanishes, and freedom inevitably declines. Totalitarian regimes are the monstrous, but not improbable, outcome of this process (Baehr, 2010). The antidote to the 'rise of the social' is a restoration of politics by way of a reopening of the public sphere of action and speech. Concretely, Arendt judged positively some of the experiments of democracy from below, such as the workers' councils of the Hungarian Revolution in 1956 (Arendt, 1958). They were an example of a reinvention of the political, understood as a distinct sphere of activity in which equal human beings, leaving violence and petty interests aside, present themselves to others in their singularity and freely act in concert to create a 'common world' (Arendt, 1998: 28).

Arendt's legacy is a complex one. She has been criticized for her elitist views of politics as an encounter between highly reflexive individuals unaffected by material difficulties (Wolin, 1983). Others have seen her as the most important inspiration behind the move toward a theory of participatory politics, represented by various authors of the second half of the twentieth century, from Castoriadis to Habermas (Honneth, 2000: 52, 53). At the conceptual level, interpreters have underlined the very peculiar nature of Arendt's definition of 'the social' (Pitkin, 1998: 201), which could be said to be closer to our understanding of 'the economic.' This may be the reason why the concept of 'the social' in the Arendtian sense was not taken up by other authors, and why even she later distanced herself from it. Nevertheless, Arendt's concept of 'the social' also encompasses, as one of its aspects, 'welfare state policies.' In this more limited meaning, 'the social' has become a relatively common term, both in the general public and in academic circles (e.g., Donzelot, 1984; Rose, 1996).

Another important critic of the dominant concept of society in the postwar era is Robert Nisbet. In many ways, his position was close to Arendt's, but his vocabulary was clearly a different one: in *The Twilight of Authority*, one of his later writings, he pleaded for a "liberation of the idea of the social," which he understood as voluntary association and the self-administration of local collectivities, "from the political," which he equated with the bureaucratic, militarized state of the postwar era (Nisbet, 1976: 241). Nisbet targeted especially the notion, inherited from the Enlightenment, that the state could single-handedly reshape society. This notion, according to him, was at the core of the project of the welfare state: its goal was to establish economic equality and political homogeneity by way of leveling social policies, unitary school programs, and political surveillance. The welfare state, however, made little case of local specificities and inherited traditions; it also overlooked the capacity and desire of individuals and groups to decide and act for themselves. Thus, like Arendt, Nisbet feared that the welfare state and its bureaucratic apparatus could breed mass conformity and undermine political liberty. He advocated a 'rediscovery of the social' (Nisbet, 1976: 241): in order to recover liberty and diversity, power should be "distributed into as many hands as possible," and this could be achieved only by way of a recognition of the "functional autonomy of [the] social units" that compose society as a whole, such as kinship groups or professional associations (Nisbet, 1976: 237).

'The Social' in the Late Twentieth and Early Twenty-First Century

In the decades 1980–2010, it is with the different, more general meaning of 'any phenomenon involving an interaction between distinct entities' that 'the social' became a common concept. In most cases, the entities in question are human beings, but some authors, such as Bruno Latour (2005, borrowing from Gabriel Tarde, 1999), argue that an association between animals, or between humans and things, also belongs to the realm of the social. The concept of the social has been at the center of many debates, including three especially prominent ones: the first one concerning the relevance of the concept of society (1); the second one concerning 'the social' in social history (2); the third one concerning the object of social philosophy (3).

1. Some practitioners of the social sciences have argued that 'the social,' and not society, should be seen as the proper object of their disciplines. The reason for this proposed replacement is a dissatisfaction with the assumptions typically built into the concept of society. 'Society,' its critics argue, is commonly taken to be an economically and culturally self-sufficient and stable entity with clearly delineated boundaries, a centralized political apparatus, and a homogeneous culture. Even though each of these assumptions has been challenged since the beginning of the social sciences, the critique of 'society' has become more prevalent since the 1970s. This is partly a reflection of new social developments. First, the rise of political dissent and social movements in these years (from the civil rights movement to the mobilizations that shook Eastern Europe) undermined the notion of society as a homogeneous, consensual block: new approaches in the

social sciences emphasized power, conflict, and violence (e.g., Foucault, 1975; Mann 1986–93; Tilly, 1990), or alternatively movement, creativity, and communication (e.g., Touraine, 1984; Joas, 1996). Second, the acceleration of the globalization process inspired many sociologists and political scientists to theorize the existence of social relations across societal boundaries, thereby challenging the assumption of a strong boundedness of society and the common equation of the social with the national (Chernilo, 2007). Already Frederik Barth (1969) had made the observation of continuous exchange across boundaries: this forced him to envisage social boundaries as porous and in permanent need of reinforcement and maintenance. With the increasing challenge to the nation-state, especially in Europe due to the Europeanization process, some authors started to advocate a 'cosmopolitan' or 'transnational' turn in the social sciences (cf Beck and Sznaider, 2006). These developments have created a fertile ground for conceptual change. Many authors have suggested new, alternative terms to avoid the problematic connotations of 'society' (cf Wagner, 1999; Turner, 2006). Without dropping 'society,' Bourdieu (1985, 1989) spoke of the 'the social space,' the 'social world,' and – occasionally – 'the social' (cf Calhoun, 2005). Mann (1986: 1) proposes an "organized power network." Some authors went further and emphasized 'the social' over 'society.' Raymond Boudon, the representative, in France, of rational action theory, published an introduction to sociology under the title *The Logic of the Social* (1979; English translation: 1981). The avoidance of the concept of 'society,' which Boudon, like many other methodological individualists, saw as the fetish of deterministic, holistic sociology, is revealing. At a different end of the sociological spectrum, John Urry (2000) argues that sociology should move beyond 'society' as the subject matter of sociology and focus instead on 'the social,' which he conceptualizes as the movement of persons, things, and signs within and across boundaries. In a similar vein, Latour also gives to the concept of 'the social' an especially prominent role. In *Re-Assembling the Social* (2005), he argues against the assumption that 'social causes' – in the form of ideologies, objective interests, or cultural representations – determine the action of individuals. He contrasts 'the sociology of the social' with his own 'sociology of associations.' The first one assumes that the action is caused by factors that are external to it, and views the social actor merely as a transmission belt of extant structures. Latour, following in the track of ethnomethodology, envisages the social as a permanent flux: competent actors constantly mobilize their intelligence to act in a complex environment: action is the result of a local process of negotiation with other individuals and things. In order to account for the enduring character of certain social phenomena, Latour suggests that face-to-face interactions (which Latour calls 'the social 3') are constrained by the presence of 'the social 2' – which is the material traces left by former actions, such as buildings, roads, words, and machines. More than society, it is these elements, as well as their associations in 'networks' and 'collectives,' that should be, according to Latour, at the heart of the sociological discipline.

2. A related line of critique of 'social explanations' and of 'society as a reified totality' (Sewell, 2005: 322) can be found in the work of critical historians such as Patrick Joyce (2002, 2010) and Michael Cabrera (2004, 2005). According to these authors, the dominant form of history-writing after 1945, social history, relied too heavily on social structure (especially the relations between classes) in its attempts at explaining social events: there had been a tendency to assume that a given configuration of the social automatically yields given historical events (for instance, the rise of the bourgeoisie causes a bourgeois revolution): the question of agency is discarded, and culture is perceived as a mere reflection of the social structure. Even after the 'cultural turn' of the 1970s and 1980s, many historians overemphasized the stability and homogeneity of collective representations and failed to include a consideration of the process of cultural production and transformation. Joyce and Cabrera advocate a serious engagement with the concepts of 'culture,' 'society,' and 'the social,' in order to avoid any reification of the realities they are taken to denote. Finding inspiration in the work of Michel Foucault and Charles Taylor, Cabrera suggests that historians should focus, not on society and the social, but on 'discourse' and the 'social imaginary.' 'Discourses' are impersonal, collective sets of representations which entail 'concepts, categories, and principles' and more generally 'meanings' with which to 'apprehend and conceptualize reality' (Cabrera, 2004: 22, 23). They play the role of a 'repertory' for individual and collective thought and action, thereby limiting their possibilities. At the same time, social actors actively select and combine elements from the discursive frame, so that they are not determined by it. Even though the abandonment of any notion of social causation and the rehabilitation of agency represents a shift away from classical social history, Joyce and Cabrera can be said to remain located within the paradigm of the social: as 'things' *shared* between various individuals, discourses and imaginaries pertain to 'the social,' in the sense of 'the complex interdependence' that characterizes 'human interrelationships' (Sewell, 2005: 365).

3. Among social philosophers, some authors have indicated 'the social' as that which should be the main focus of attention. This is the case of Axel Honneth. In his programmatic delineation of the identity of the discipline (2000; English translation: 1996; see also Honneth, 1995), he discusses a range of authors from Rousseau to Arendt, Habermas, and Castoriadis. He argues that one of the central themes of social philosophy has been the identification of some 'pathology' or dysfunction in human collectivities that prevents individuals from pursuing their own vision of the good. The 'healthy' social, by contrast, is a form of "normality tailored to conditions that enable human self-realization" (Honneth, 1996: 36). These 'conditions of self-realization' can be variously defined: historically speaking, philosophical anthropology has formulated different answers to this question, from Rousseau's emphasis on independence to Arendt's defense of collective speech and action (cf Jörke, 2005). Honneth himself, finding inspiration in Hegel, has developed a complex anthropology of recognition. In an argumentation that bears some resemblance with Arendt's, he argues that any society that structurally inhibits the recognition of the equal value of persons is bound to become bereft with various pathologies, including permanent individual suffering. In this line of reasoning, it is not society as a whole

which is at the center of social philosophy, but 'the social,' understood as the conditions under which individuals can live a decent life, in association with others.

Conclusion

Looking back, two developments of 'the social' can be highlighted in particular. First, 'the social' has acquired a meaning of its own, thereby becoming more independent of 'society': a more abstract term applicable to the macrolevel, as well as to the microlevel, and with less connotations of homogeneity and boundedness, it is even often described as an alternative to 'society.' If we take into account computing and information technology ('social networks,' the 'social Web'), it appears that 'the social' has recovered some of the connotations it had at the very beginning: connotations of companionship, collaboration, exchange, and freedom. Second, the importance of this concept has steadily grown, so that it has now become one of the central notions of social science. However, this did not happen without resistance. 'The social,' an 'exceptionally complex or polysemic concept' (Sewell, 2005: 324), has been at the heart of heated debates in the social sciences, with positions ranging from downright condemnation to very positive appreciation. Historically, the rise of 'the social' should be understood against the background of the impact of antiessentialist and antirealist approaches in the social sciences (cf Elder-Vass, 2012; Hacking, 1999). In the spirit of Simmel and Weber, these approaches describe social phenomena not as objective 'things' but as outcomes of social constitution processes; moreover, a widespread social belief in these entities is crucial to their emergence and stability. Thus researchers have introduced new concepts which indicate a shift of focus from clearly circumscribed things (such as the state, religion, or 'society') to more abstractly defined general phenomena (such as the political, the religious/the sacred, or 'the social').

Socialism

Abstract

In the literature of the Social Sciences, the word 'socialism' is often qualified with, or characterized by an adjective – 'utopian,' 'scientific,' 'democratic,' 'parliamentary,' 'Fabian,' 'evolutionary,' 'revolutionary,' 'Christian,' 'Guild,' 'actually existing,' and 'market.' (Additionally, one can read of socialist internationalism, realism, feminism, etc.) This article investigates the common ground or substratum these various characterizations of 'socialism' (or 'socialist') share by tracing out the historical emergence and provenance of the term.

Leszek Kolakowski's survey (1978) calls attention to "the surprising diversity of views expressed by Marxists in regard to Marx's so-called historical determinism." However, what is 'surprising' is not this diversity – which becomes much wider if we examine not Marxism in particular, but socialism in general. The surprising thing is Kolakowski's pontifical belief that faced with it he could "schematize with precision the trends of twentieth century Marxism" (1978, Vol. I, pp. 6–7). His failure to attain such precision serves as a salutary warning to anyone attempting to characterize the broader and much more 'diverse' terrain of socialism, of which Marxism – nineteenth- and twentieth-century Marxism – is itself but a 'main current.' In what follows, which will (in Wittgenstein's words) 'strive *not* after exactness, but after a synoptic view,' attention will be paid to Cole's admonition: that "the most that can be attempted is the discovery of some central core of meaning, present with varying additions in all or most of the manifold uses of the word (socialism)" (Cole, 1967: vol. I, p. 1). This entails sensitivity to the shifts in meaning that socialism has undergone since its inception; only beneath these shifts can a substratum of meaning emerge.

Capitalism, Socialism, and Democracy

The word 'socialism' first appeared in Robert Owen's *Co-operative Magazine* in 1827, *le socialisme* in the Saint-Simonian journal *Le Globe* in 1832. It meant a projected alternative sociopolitical system – this was still offered as a definition of 'socialism' in the 1933 OED – not a political movement or demand. Early socialist doctrine contained little about the proletariat, the class system, labor, or revolution. While John Stuart Mill's *Principles of Political Economy* accordingly distinguished socialism and communism as theories, not political movements, Marx and Engels's *Manifesto of the Communist Party* of the same year (1848) identified communism as a movement that would render socialism, so defined, beside the point because it was merely a theory – utopian, that is, because it was impracticable. It was communism, not socialism, that carried with it the idea of revolutionary struggle and human agency; a new and better society could not be wished or legislated into existence by benevolent doctrinaires, but had to await the advent of a politically conscious, class-based labor movement. This was a key shift in the coordinates, not just of communism, but of socialism. It too had now to be not just thinkable, but feasible. After the failure of the 1848 revolutions, communism ceased for many years to be practical politics, yet some time was to pass before Marx and Engels consented to having their cause described as "socialist" (Lichtheim, 1969: p. 209). They did so because socialism had become not just a doctrine but a movement. Thereafter, "Marxism created that distinctively German socialism which was soon to assume an ideological dominance over most of the continent, driving the older forms of socialism before it as chaff before the wind" (Cole, 1967: vol. I, p. 222).

The second key shift in the coordinates of European socialism occurred in 1917, when, against all the odds, communism in its Leninist form arose as a clear alternative to democratic socialism – the same democratic socialism that had itself, against all previous odds, survived World War One. Both authoritarian communism and democratic socialism laid claim to a lineage deriving from Marx; but they had little else in common. Twentieth-century communists showed no reluctance to clothe their particular doctrines in the broader mantle of socialism. The locutions, 'Union of Soviet Socialist Republics,' 'socialism in one country,' 'socialist realism,' 'socialist internationalism' (in its twentieth-century Soviet version, which meant subservience to the foreign policy of the USSR), the fact that after World War Two the East German Communist Party was officially called the 'Socialist Unity Party' – all these are instances of synecdoche, if not the sheerest verbal trickery. We should not allow them to addle us into thinking, languidly, that all twentieth-century communists were socialists, whereas not all socialists were communists. There were in the twentieth century not just noncommunist but also anticommunist socialists aplenty, socialists actively and vociferously opposed to communism, from the very moment when such opposition first became possible, at the Berne International in February 1919, when adherence to democracy was reasserted as a prerequisite for socialism (Cole, 1967: vol. IV, pp. 292–299). The socialism that survived World War One to become part of the European political landscape had had as its prerequisite not democracy but capitalism. Socialists had long been in the forefront of the struggle for democracy. (Indeed, socialism was weakest in those countries, the United States and the United Kingdom, where it was a less powerful force in the struggle for

democracy than it was on the European continent.) In Cole's words, Liebknecht, Bebel, and Kautsky in Germany, Guesde in France, indeed, most socialist stalwarts in Europe before World War One "felt that they had no *right* to make the revolution without the backing, or at least the assent, of the people. They thought of the proletariat as being, or as in the process of becoming, the majority of the people; and they envisaged the mass conversion of the proletariat to the socialist cause as a necessary preliminary to the revolution" (Cole, 1967: vol. III, pp. 946–947). This democratic perspective was not necessarily reformist or purely parliamentary; democratization was also meant to encompass work relations and trade union structures, and could scarcely have avoided doing so. What the Second International socialists rightly feared was war; the solitary success of Russian Bolshevism in 1917 was as little expected or foreseen as its eventual collapse was to be in 1989.

Marx, Marxism, and Socialism

Marx casts a longer shadow over the history of socialism than anyone else – not because every socialist agreed (or was even very familiar) with what he said, but because, all the same, his presence proved impossible to ignore. It is in this sense that Marxism can be called the *lingua franca* of socialism (Cole, 1967: vol. I, p. 379). Without Marx, we would still have had revolution as a word and as a concept, as the French and the Americans had put revolutionary change on the political agenda during the eighteenth century, and we would have had capitalism, socialism, communism, and (thanks to Babeuf) the proletariat too. The celebrated opening line of the *Manifesto of the Communist Party* was designed to call the reader's attention to 'the specter haunting Europe,' to invoke, not invent, communism. It is no doubt easier to imagine a world without Marx than a world without revolution, capitalism, communism, and socialism. But in the world we actually inhabit, all these still have to be seen through Marx. He may not have coined these terms, but he decisively set his seal on them. They still cannot properly be discussed without bringing him in. Marx contributed enormously to the vocabulary of socialism (class, class struggle, class war, class consciousness, ideology, alienation, the commodity, forces, relations, and modes of production, exploitation, contradiction, and crisis). Even though "socialist and communist movements (took) up some aspects of Marx's theory and discarded others, even this selectivity (was) carried out in Marx's name" (Gilbert, 1981: p. 270).

Yet much that was carried out 'in Marx's name' was attained without much knowledge of what he had written. The revisionism debate (at the turn of the twentieth century) that almost tore apart German Social Democracy and the Second International was about Marxist 'orthodoxy,' but was conducted in an astounding ignorance of Marx's writings. Although practicing politicians commonly regard themselves as having more immediately pressing concerns than questions of textual fidelity, these same questions were never ignored among Marxists – although the theoretical corpus to which socialist stalwarts appealed was not necessarily made up of Marx's writings. The problem was not that a canon of basic texts failed to emerge. (To the contrary, textual fidelity was adhered to tirelessly – and, at times, tiresomely.) It was that the canon as it developed was not so much derived from what Marx had written as it was constructed around what little of Marx was available in published form. Historical materialism – it still amazes people when they learn that this term was not Marx's own – had its basic texts long before the first appearance in any language (during the 1930s) of so basic a text as Marx and Engels's *The German Ideology*. These texts included Franz Mehring's *On Historical Materialism* (1893), G.V. Plekhanov's *The Development of the Monist View of History* (1895), Antonio Labriola's *Essays on the Materialist Interpretation of History* (1896), and Karl Kautsky's *The Materialist Interpretation of History* (1927). Even though Marx in some sense inspired these books and others like them, what he had to say eventually needed to be disentangled from their arguments. It could in no way be directly encountered through them or explained by them (Thomas, 1991: pp. 32–33).

The Varieties of Socialist Experience

Even if Marx was more known about than known, the fact remains that by the end of the nineteenth century a politically oriented, class-conscious European socialist movement had emerged in his name; and by this time the word socialist meant what it still means today, a social and political doctrine and a political movement or system. In view of this latitude of meaning, it is scarcely surprising that 'socialism' has come down to us in social science literature as a noun qualified by an adjective – as in 'utopian socialism,' 'scientific socialism,' 'state socialism,' 'revolutionary socialism,' 'evolutionary socialism,' or (until recently) as 'actually existing socialism,' or again (today) as 'market socialism.' Similarly, the adjective 'socialist' can be employed as a pendant qualifying or characterizing an abstract noun, as in 'socialist internationalism,' 'socialist economics,' 'socialist realism,' or 'socialist feminism.'

The above-listed collocations – the inventory is illustrative, not exhaustive – are not just convenient subdivisions, but serial attempts at spot-welding that can readily be arrayed in historical sequence. 'Utopian socialism,' as we have seen, dates from the 1830s and 1840s, 'Fabian' or 'evolutionary socialism' dates from the late nineteenth and early twentieth centuries, 'Guild socialism' dates from the period between the two World Wars, and 'actually existing socialism' dates from the latter days of Soviet communism. 'Socialist internationalism' peaked, then bottomed out dramatically, in the period before 1914; 'socialist realism' (like 'socialism in one country') belongs to the Stalinist period in the Soviet Union; 'socialist feminism' to Western scholarship of a later date. To array these composite terms historically in order to arrive at the meaning of their least common denominator, socialism, is not to pigeonhole them arbitrarily, nor yet to proceed reductively, if it is borne in mind throughout that each instance of spot-welding affected the coordinates of its successors.

More specifically, anarchism, syndicalism, and their offshoots (whether revolutionary or not) are kinds of socialism that were defined and elaborated against state socialism (Thomas, 1980); Engels in 1875 contrasted scientific with utopian socialism (even if the latter was largely a spent force,

the former was to enjoy some shelf-life well into the twentieth century); Lenin defined Bolshevism, then communism as he understood the term, against the parliamentary, reformist socialism of the pre-1914 German SPD (and by extension the Second International); this reformist socialism had itself been elaborated in contradistinction to the revolutionary socialism that appeared to have had its come-uppance at the time of the Paris Commune (1871). Lenin's successors proceeded to counterpose socialism in one country against the socialist internationalism the First and Second Internationals had espoused. Overall, these developments do not add up to a tidy, formulaic picture. Yet there is a subtle patterning in the carpet. Positions and tendencies throughout the history of socialism were debated, articulated, and defined in relation to other, pre-existing socialist positions and tendencies.

Abstract

In the nineteenth century, socialism scared governments. By around 1900, it was the main anticapitalist current worldwide. It aimed at simultaneously humanizing and replacing capitalism. Confusions implicit in that simultaneity were aggravated by an illusion that socialists could prevent wars. That illusion exploded in 1914. Russia's Bolsheviks alone proved able to make peace, but this was founded on another illusion that socialists in developed countries would rescue them. Their resulting desperation nurtured their least democratic aspects, helping to polarize the world ideologically, until the Soviet Union collapsed in 1991. This collapse boosted doubts about further humanization, let alone the replacement of capitalism by socialism.

Forerunners and Pioneers

The word 'socialism' emerged in Britain around 1830 and in France during the 1830s, denoting a society that would not have individualism and private profit as its motive power: what it would remains harder to define. In Britain, it was first publicized by the humbly born Welshman, Robert Owen (1771–1858), who had made his fortune as an industrialist in Manchester, the 'shock city' of industrialization, before moving to New Lanark, near Glasgow. Here, he had made his name as a paternalist employer. He boosted profits by cutting the working day, thus refuting those economists who saw them as dependent on the 'last' hour of a very long one. He subjected employees to psychological pressures, more frequently positive than those applied in rival firms. He also housed them to high standards and, for him even more vital, offered them space for recreation, plus free schooling for all children and adults. Pedagogic methods were strictly Enlightenment, aiming to nurture Reason.

Mid-eighteenth-century Britain was at the forefront, both of what is nowadays called the industrial revolution and of 'laissez-faire,' i.e., free-market economics. Some writers, such as the multidimensional autodidact William Blake (1757–1827), denounced Northern England's 'dark Satanic mills,' and linked them to ruthless free-market contempt for the London poor. Similar unease grew in France, not only about being outpaced but also because similar processes were spreading there too, as also in the neighboring Prince-Bishopric of Liège.

But where were coherent alternatives? Equalization of incomes among early Christians was sometimes gestured to. Totally unknown, by contrast, was the practice of collective ownership among, say, sixth-century followers of the Iranian reformer Mazdak. European hindsight may recognize partial foreshadowings of socialism among the radical wing of the Hussites in fifteenth-century Bohemia, by the Anabaptists in 1530s' Munster and more coherently by the Diggers in England around 1650. These three movements were all more or less against private property, whatever their religious dissimilarites.

Fantasy was many centuries old about an ideal society which, in 1516, the Greek-speaking Sir Thomas More had playfully named *Utopia*, i.e., both 'good place' and 'nowhere.' It remained sufficiently lively in eighteenth-century Britain for satirical inversion. The Grand Jury of Middlesex testified clumsily to this by ordering the ceremonial burning of Bernard Mandeville's 1723 *Fable of the Bees*, thereby publicizing his claim that morality and what we would call capitalism were incompatible.

Nineteenth-century pioneers of 'socialism' defined themselves in relation to earlier writers and movements and, in particular, as furthering Enlightenment emphases on Reason against superstition. Some recent scholars (e.g., Margaret Jacob, Jonathan Israel) have distinguished 'Radical' and 'Moderate' Enlightenments. The latter, as typified by Voltaire's cultivation of enlightened despots such as Catherine of Russia or Frederick of Prussia, sought reform from above. Its 'radical' and often older (*c*.1700) rival sought much wider support, was more outspoken, was more censored (at least in the Netherlands), and is therefore, partly as a result, less visible. The 1797 'Conspiracy of Equals' was one late heir of that tendency: Francois Babeuf (who renamed himself 'Gracchus,' after two ancient Roman radicals) was guillotined along with most other members for conspiring against France's individualist Republic. The chasm between Voltaire and Babeuf, between from-above and (would be) from-below, can symbolize some of the key problems of definition, agency (i.e., who is seen as bringing what to whom), strategy, organization, and thus of democracy. Not least, if you feel driven to conspire to seize power before handing it over to the oppressed masses, what if they do not grasp your generosity?

For Charles Fourier (1772–1837), the Babouvistes' blunder had been to act politically at all. Fourier, a merchant's son who had grown to loathe everything mercantile, insisted on tackling what he called the 'social question' directly. He posited 12 'passions.' 'Passions,' David Hume had argued (1739), should have 'reason' as merely their 'slave.' But, from 1789 to 1790, conservatives had seen them as grotesquely freed by revolution: only Christianity might cage them again. Yet Fourier daringly made them into the motive power of a radically new society. Via their 'gravitation,' he derived – with, for him, the cool logic of a Newtonian scientist – 810 personality types or rather, given two 'sexes,' 1620 types: ideally, therefore, that was the number of members for each of his communities, or 'phalanxes.' These

should build 'phalansteries' as soon as possible. He thus sought to transpose utopia from libraries into practice. Two vital requirements were (1) to end marital rigidity and gender division of labor, thus allowing women as well as men to unfold themselves and (2) to use the latest technology for flexing all such divisions, including those between work and education. Respectability drove most followers to downplay the gender aspect. He had also embarrassed them with his aim of reforming Nature: his 'seas of lemonade' are still flowing. Yet he was not the first such Natural reformer: the Digger leader Gerrard Winstanley and, some decades earlier, the much-tortured Tommaso Campanella had preceded him. So the reception of Fourier's ideas was distortive in many ways. Later, though, socialists and others would applaud his characterization of laissez-faire as tending to monopoly, to mass impoverishment, and thus to what would later be called crises of overproduction.

Unlike Fourier, Owen embraced the frequent Enlightenment assumption that characters were 'formed by environment.' By reforming that, you reformed them. This, he felt, entitled him to hope that his 'Social System,' as he called it from 1813, could be introduced by existing power holders. Some indeed showed interest. But this evaporated when his 1819 *Report to the County of Lanark* showed him not to be Christian. Almost worse, he rejected marriage as cruel, not least for women. From the 1820s, he began to attract a wider following, mainly among members of trade unions (slowly emerging from a generation of illegality) and among self-educating poorer people. His predicament was sometimes odd: a big employer and believer in his own from-above superiority, serving as figurehead for organized workers, some of whom were moving toward ideas of replacing capitalism by means of a general strike (a strategy later dubbed 'syndicalism'). Others, by contrast, continued calling him their 'Social Father': uniquely superior to them.

Internationally, the 'Owenites' were hardly alone in falling into this prophetic dynamic. In France, the gap between leader and followers was often no less striking. From 1817, Claude-Henri de St Simon (1760–1825) was pamphleteering for rule by enlightened banker–industrialists. As with Owen, industrialization was not a disaster but the door to a new society. St Simon's word for the latter was, not socialism, but 'industrialism.' Here, scientists would replace priests as the elite. Thus, he was at least as top-down as Owen. But, like the Welshman, he and his successors gained followers among poorer groups whose approach could be far more bottom-up.

Nor did all such groups necessarily have to wait for better-off leadership. In Britain, one late example of Radical Enlightenment is the impoverished Newcastle (later London) street bookseller Thomas Spence (1750–1814). His repeated imprisonments on charges such as high treason helped him avoid invisibility. By the end of his life, his 'Spencean' followers, some of them trade unionists, were demanding socialization of a growing number of industries. From 1771, Spence had envisaged all land being owned by parish communities, which would rent it out to individual members. All members, women as well as men, would have one vote for the parish council and for the national senate. All those unable to work would be guaranteed free food and board. Abolishing private landownership would by definition abolish aristocracy, the House of Lords, and much else. Class would be further fought by a new phonetic alphabet: not only undermining accentual snobberies but also easing education and self-education. For Spence, all this would constitute 'the real rights of man,' a phrase he had used before Tom Paine's more readable but less collectivist two-volume defense of the French Revolution (*The Rights of Man*, 1791–92).

Owenites, like Fourieristes, sometimes tried to withdraw from political action of any kind within the Bad Old Society, founding exemplary communities. These would act as beacons of the New Social System, spreading it by example. Few did; most collapsed messily. Disillusion lasted into the next generation of socialists, typified by Karl Marx (1819–83) and his manufacturer–friend Friedrich Engels (1820–95) who scornfully labeled their predecessors 'utopian socialists.' The label spread to almost anyone who attempted to specify what the new society might look like. Sketchiness about aims is thus a frequent indicator of Marxist influence: apart from 'socialism' constructing 'communism,' one should not bind future comrades.

More positively, some poorer Owenites, particularly in industrial Northern England, moved toward erecting their own cooperative economy. In this, their nearest French equivalents would be the followers of Pierre-Joseph Proudhon (1809–65), a self-taught proofreader and sometime admirer of Fourier who, apart from coining the resounding motto 'Property is Theft' (1840), sketched a 'mutualist' system: workers' cooperation underpinned by low-interest banks.

As in England with some of Spence's followers, so in France, intellectual self-confidence propelled many artisan socialists into sympathy with radical conspiratorialists such as Auguste Blanqui (1805–81). Blanqui related resoundingly to a world of political clubs which, thanks to repression often fiercer than in Britain, met secretly. He himself was of respectable origins, but moved swiftly from what can be labeled social republicanism toward socialism: in British terms, from Paine to Spence. Not that his milieu lacked apostles of one or other utopian tendency. But many of them were themselves moving toward conspiracy, and Blanqui himself conspired tirelessly. He accumulated 35 years of detention and one death sentence. By around 1860, he was in effect strengthening anarchists such as the Russian Mikhail Bakunin (1814–76: possibly the first self-described 'anarchist') in their suspicion of mass organization and in their principle of 'Neither god nor boss.' His coup attempts could mobilize hundreds of conspirators. Into the early twentieth century, he attracted respect from some of those socialists who had been forced into illegality – as in Russia – including from the young Vladimir Ilyich Ulyanov, better known as Lenin (1870–1924). The majority of identifiable activists in the Paris Commune (1871) saw themselves as more or less Blanqui's followers: his election as the new regime's President was no surprise. That the rightwing government had detained him shortly before removed an instinctive military organizer while sparing him from massacres perpetrated by its own troops.

In France and by Blanqui's death, his followers and those of Marx were merging. They did so more tightly in 1898, by founding a Revolutionary Socialist Party. But this organization was hardly alone. Of greater long-term importance was the slogan that Blanqui had launched during 1870 against both the

rightwing Provisional Government and the advancing Prussians: 'la patrie en danger.' France, as in the early 1790s, remained the 'fatherland' of revolution. His cry was destined to smooth many French socialists' slide from internationalism to patriotism during the crucial days around the outbreak of war in 1914.

As such, a vibrant link between the early-middle and late nineteenth century, Blanqui had no equivalent in Britain – if we omit some Irish nationalists – whose stances on socialism varied. The Owenites had declined from the 1830s. The main political movement was for one-man-one-vote democracy, concisely formulated in the 'People's Charter.' Some 'Chartists' such as James Bronterre O'Brien (1805–64) were open to socialist ideas, although very few to most then-socialists' feminism. But few wished to spend time defining the root-and-branch reforms they all expected to bring about, once parliament had democratized itself: a stage never reached. Their differences over aim were anyway separate from those on strategy, thus guaranteeing further confusion. By around 1900, Europe's strongest socialist parties were to have their own press and engage constantly in mass petitionings and demonstrations, occasionally in political strikes, not least for the vote, and so had Chartists during the 1830s and the 1840s, sometimes massively, but without commitment to socialism.

Tighter trade unions of 'skilled' men were emerging in Britain from the 1840s. Their stability and moderation were a standing refutation of predictions in Marx and Engels' 1848 Communist Manifesto that intermediate groups would fall through a widening chasm between capitalists and an ever-swelling majority of the population, seen as 'proletarian' in Marx's sense of still powerlessly poor, but destined to overthrow capitalism because increasingly networked in and between large workplaces. Nevertheless, they may have felt flattered by another prediction: of class struggle as the motor of human history between the long-forgotten abandonment of 'Primitive Communism' and the coming attainment of full 'Communism.' When the manifesto's two authors organized an 'International' of social revolutionaries, they welcomed these union leaders as counterweights to those more revolutionary than themselves, particularly Bakunin. Those who did affiliate were moved partly by the hope of combating any import of strikebreakers from abroad. But any violent perspectives for Britain itself were normally anathema to most of them. Consequently, when Marx hailed the Paris Commune as an example for all proletarians anywhere, they mostly walked away in disgust: not for them a 'dictatorship of the proletariat,' with constant from-below democracy plus instant dispossession of the possessors. This walkout removed Marx's anti-anarchist counterweight. So he and Engels arranged for the International's headquarters to move to New York, then still sufficiently peripheral for quiet burials (1878).

A Social Democratic Party Cosmos Shatters

By the time its successor, seen as the 'Second International,' was formed on the hundredth Bastille Day (1889), much had happened. Not least in Germany. Here, the model emerged for which socialists worldwide long aspired: of a 'Social Democratic' Party (SPD), linked to a trade union movement and committed to replacing the capitalist system, even while working within it so as to improve social and working conditions in the here and now. True, there was some perspective that these improvements were themselves bringing socialism nearer. But tensions between the long and short terms were destined to complicate politics within any national capitalism. Worse, in 1914, they helped hollow the commitment of most socialists to internationalism: few gladiators supported demolishing their national arena. That revelation was to split socialists till nearly all 'communist' states collapsed in 1989–91. Twentieth-century socialism became an interaction between two socialisms: Communism and 'Western' Social Democracy.

So widely and lengthily can the SPD's incoherences be said to have reverberated. They can partly be traced back to the antics of one hyperactive polymath, Ferdinand Lassalle (1825–64). In 1863, he had helped founding a General German Workers' Association. In 1875, this had formed what soon became the SPD, jointly with followers of Marx. These, too, proved open to Lassallean hopes of using the existing – in Germany, highly illiberal – state for socialist purposes. Lassalle (who had irrelevantly perished in a duel) had even been prepared to ally the working class – publicly with poorer peasants, but privately with the aristocracy. Perhaps fewer SPDers would have remained under his posthumous influence, had they known more details of his contact with the Prussian (soon German) Chancellor, von Bismarck. The latter saw socialists among his main enemies, not least for their avowed internationalism. His strategy evolved into: granting universal male suffrage, but to a still weak parliament on a franchise, which disadvantaged working-class voters; social insurance and similar reforms as further sweeteners; and, from 1878 till he retired in 1890, a series of Anti-Socialist Laws. These were designed, not to outlaw the SPD directly, but to impede its workings and harass its leaders. Resoundingly, Bismarck's strategy boomeranged: repression boosted legitimacy so much that, by 1890, the Party enjoyed a vote larger than any rival and, by 1914, a membership over a million. Its 1891 program, crafted jointly by the fount of Marxist orthodoxy Karl Kautsky and his soon increasingly 'revisionist' comrade Eduard Bernstein, had by 1914 enjoyed translation into 16 languages.

It echoed themes heard internationally in 1889 Paris: mass mobilization for obtaining universal suffrage; support for all social reforms and any dispossession of private capitalists, thereby accumulating something that would somehow abolish capitalism; economic equality between women and men ('equal work, equal pay': a phrase slipperier than at first assumed); opposition to war. By 1914, the key tension between reforming capitalism and seeking its overthrow was obsessing many SPD intellectuals, with Kautsky defending existing principle, whereas Bernstein offering elegance too honest for most: "the aim [was] nothing; the movement everything." Only a handful, such as the internationally much-experienced Rosa Luxemburg, tried formulating revolutionary strategies such as the General Strike.

Such debates were hardly unique to Germany. But few countries had a comparable evolution. In Britain, long the most industrialized, avowed socialists had been few and weak since the collapse of Owenism, although by 1890 they were indulging in splits. Some, however, did settle down to allying

with trade unionists, irrespective of 'isms.' The result was a 'Labour Party' that, from early 1918, had a membership both individual and affiliated via a growing number of unions and, via the famous 'Clause 4' of its 'Constitution,' a commitment to "securing to the workers … the fruits of their labor, by means of the socialisation of production, distribution and exchange." 'Socialization' was deliberately ambiguous, dodging divisive clarities such as 'under workers' control.'

By contrast in Italy, little industrialized outside some Northern cities, the Socialist Party was by 1914 attracting 3 million votes, mainly from small-town artisans and, particularly in the landlord-ridden South, peasants. In France, another very different story, state repression after the 1871 Commune had given socialists many martyrs and exiles, but little unity or membership: low membership was to persist among trade unions and socialist parties into the twenty-first century, although punctuated by explosively widespread solidarity. In Iberia, actionisms such as anarchism fed on centuries of absolutist repression and intrusive Catholicism – all confirmed, at the start of the nineteenth century by a war of national liberation against an avowedly progressive invader (compare 1980s' Afghanistan?). But exceptionally, industrialized parts of Catalonia were able to produce a far richer range of tendencies.

Scandinavia and the cities of Bohemia and Austria produced labor and socialist movements comparable in local strength to the German, and usually modeled on it. Until Austrian Fascists crushed them in 1934, they inspired reformers, notably in Scandinavia and Britain, with achievements in housing, welfare, and education. Their intellectuals tried to upstage problems of nationality by uncoupling it from territory to link it to personal choice.

Further afield, socialism, anarchism, and (as in the 'Industrial Workers of the World') syndicalism in the continents of massive migration from Europe often remixed all the trends and tendencies in home countries, intensified during explosive strikes. Whatever the verbal commitments to internationalism, ethnic relations among people of European background varied. Invariably, 'nonwhites' were seen as inferior and, self-confirmingly, as wage cutters. 'Workers of the world unite and fight for a white South Africa' was already the strategy of militant Johannesburg strikers during 1913, 9 years before the slogan arrived with a more vast upheaval in 1922. Only during the 1920s was one self-taught Peruvian, J.C. Mariategui, to try reformulating Marxism so as to take account of non-European, here Andean, social forms. His early death (1930) guaranteed that every side in an increasingly split world movement would distort his legacy, till perhaps the 1990s.

By 1914, the main danger was of drift toward war. Socialists defined themselves as antiwar. When the International's 1904 congress coincided with a Russo-Japanese conflict, Georgii Plekhanov and Sen Katayama had publicly embraced. But machine guns do not embrace: what could socialists do? During 1905, Sweden's unions and Social Democrats had prevented their militarists from crushing Norwegian independence. In Belgium and elsewhere, general strikes had won men's right to vote. In many workplaces, 'syndicalism' was also lively. So the Second International proclaimed an 'international general strike' for the event of war. But the phrase remained nebulous. From July–August 1914, it contrasted cruelly with the penalties threatening male workers for resisting conscription (outside Britain till 1916, universal). Many reasoned that they were defending a less reactionary regime (e.g., French, German) against a more (respectively, German, Russian). Blanqui's 'Fatherland' remained 'in danger.'

At first, only tiny minorities resisted this logic. They were least tiny in the Russian Empire and, most bravely, in the already embattled Balkans where sectarian massacre and competing expansionisms had become traditional.

Russia proved strategic. Here, even though Marx himself had wavered, most Marxists had gravitated to his and Engels' own normal version of history: only when an old 'mode of production' had 'exhausted all its possibilities' would it be replaced. Thus, a society could not jump from 'feudalism' to 'socialism' over the 'capitalist' stage. Reality, though, complicated such stageism: Russia's large cities contained some world league factories but were lapped by oceans of peasants who had been freed from serfdom as recently as 1861. The question was how far should Marxists encourage the industrial minority among the exploited masses to go? Wars, by 1905 in the Far East and from 1914 along the Western and Caucasian borders, underlined that question: the Tsarist Autocracy was hopelessly hierarchical and worse. Stable answers had only come slowly from the various Marxist factions but, by 1914, the 'Mensheviks' (because in the 'minority' at one Social Democrats' conference) believed that a capitalist parliamentary regime was the maximum possibility, whereas Lenin's 'Bolsheviks' ('majority-ists') sometimes hoped for more, given the right circumstances. Both factions were fluid. Lev Bronstein ('Trotsky') was maneuvering in between, but had earned prestige during the 1905 revolution, presiding over the St Petersburg Workers' Council (Russian: 'Soviet'). In 1906, he had also launched the flexible phrase 'uneven and combined development' for those paradoxes of Russia's then unusual semiindustrialization.

February 1917 swept autocracy away. At this point, most Mensheviks were for continuing the already disastrous war so as to 'defend the Revolution.' Many Bolsheviks, including Joseph Djugashvili ('Stalin') remained confused. Only when Lenin returned from exile (April 1917, soon joined by Trotsky), did they begin evolving a policy that he finally sloganized as "Peace, Land [for the peasants], Bread [for the cities]." This was the program on which the mainly Bolshevik-led revolution of October 1917 was mounted, with the support of key soviets in Petrograd (St Petersburg's wartime name) and soon elsewhere. Socialists in industrial countries would rush revolutionarily to the rescue: that hope, which Trotsky had voiced as early as 1905, now proved short lived.

For 'Peace,' negotiations opened at Brest-Litovsk with Germany and its allies. The ensuing treaty cost Russia 1 million square miles, one-third of its population, and most sources of oil, coal, and iron. With such 'Peace' and such dwindling resources, the years to 1922 saw a deepening cycle of starvation, forced collection of grain from peasants triggering revolt, and further starvation. Revolts were often independent of 'white' (anti-Bolshevik) armies. A total of 21 foreign countries sent forces to help the whites. Southern Ukraine saw the largest peasant movement: no local novelty, unlike its leadership by an avowed anarchist, Nestor Makhno.

Rival Socialisms and Worldwide Diplomacy

After tens of millions of war deaths worldwide, socialists everywhere had to orient themselves more or less anew and, in relation to the Bolshevik regime, to work out their mutual identities. Lenin, increasingly incapacitated before his death in January 1924, became the fount of an emerging 'Bolshevik' orthodoxy. Under Tsarist repression, he had sometimes argued for building a tightly organized, hierarchical party. Contrastingly, during the revolutionary years of 1905–06 and 1917 when the Bolsheviks had, more slowly than Trotsky, recognized the potential of workers' and in 1917 also soldiers' soviets, he had favored flatter, more open structures, both for hastening revolution and apparently for afterward: "every cook can govern." With Civil War, workers' control of (plummeting) production lost substance, unevenly but inexorably. Just when the Bolsheviks were ascending to unprecedented influence among radical socialists, they were canonizing the least democratic version of their previous practice, while diverging from everything that most socialists had stood for. They embarked on what turned out to be the twentieth century's lengthiest and most widely delusive experiment in political monopoly. Not the bloodiest: that honor would go to Mao's China in the 1950s and the 1960s.

By the end of the Civil War (October 1922), uneven and combined collapse had replaced development. Politically, most of those industrial workers who had supported October had either died in the Civil War or had become bureaucrats. During March 1921, sailors based around the island of Kronstadt, off Petrograd, demanded complete reelection of all soviets. They were crushed as mutineers; many hundreds were executed. Trotsky commanded the forces crushing them. Two days later but deaf to irony, the shaken regime celebrated the fiftieth anniversary of the Paris Commune. The shock of Kronstadt speeded what the Bolsheviks saw as a retreat: the 'New Economic Policy' (NEP) restored a free market in grain. This eased the food situation, but only till the late 1920s. By then, the relationship between the Bolsheviks and reality at home and abroad had degraded yet further.

Abroad, however, that shock was muffled – except among anarchists, plus socialist mavericks such as the former suffragette, Sylvia Pankhurst. Partly, this muffling was due to ignorance. But what of those socialists who had seen parliamentary methods as too top-down? A few, such as Luxemburg, had warned against Lenin during his stricter phases as leading to Party 'dictatorship over the proletariat.' Her murder in 1919 hardly stopped 'Council Communists,' such as Anton Pannekoek, from arguing similarly through the decades. What pushed most socialists in the other direction, into long-term sympathy with the Bolsheviks, was a gnawing inferiority complex. Uniquely, the Bolsheviks had, apparently, 'done it': had made a revolution. True, French sailors and British dockers and soldiers had sometimes struck or mutinied against intervention in the Russian Civil War. But the very peripherality of these successes – let alone the failure of attempted or near revolutions in Germany, Hungary, Italy, and elsewhere during 1918–23 – only emphasized Russia's loneliness.

Parliamentary and other 'moderate' socialists varied from attacking Bolshevik repression, to a stance that lasted till the post-Bolshevik system collapsed. In this, you took property relations as straightforwardly defining a society's 'nature.' You noted, factually, that the means of production within Soviet society were (except during the NEP) overwhelmingly owned in the name of the toiling masses. You then deduced that this society was 'socialist' or at least 'building socialism.' True, you might lament the lack of democracy but, the louder you did so, the more you claimed to be 'doing it democratically.' Under governments such as Clement Attlee's in Britain (1945–51), 'socialization' involved no hint of democracy deeper than parliamentary.

Consensus in favor of top-down methods could also blur extremes of the socialist spectrum. Take two workaholic British intellectuals, Beatrice and Sidney Webb. Elitism and 'national efficiency' were the common threads between their pre-1918 contempt, and their post-1918 support, for a working-class party. In that year, Sidney formulated Clause 4 precisely so as to keep socialists happy. But in 1931, the two were shocked when Treasury civil servants allowed a Tory-led coalition more leeway on economic matters than, a few weeks earlier, a Labor-led one. "They never told us we could do this," Sidney protested – to his diary. He and Beatrice radicalized toward Stalinism. After their visits to Russia during 1935 and 1937, they published successive editions of their *Soviet Communism: a New Civilisation*? For 1937, they deleted the query. Thus, where Bolsheviks had impressed many previously libertarian socialists for actually doing 'it,' so their Stalinist successors appealed to Western despair about capitalism ever recovering from economic depression. In the upside-down world of Stalinist propaganda, Soviet industrialization was reaching unparalleled heights of efficiency. 'Planning' and 'efficiency' became keywords in most versions of socialism. Thus, in 1959 or roughly halfway through capitalism's longest-ever boom, British Labour's leader Hugh Gaitskell was postered as 'Man With a Plan,' and his more leftwing successor Harold Wilson enthralled the 1963 Party conference with eloquence about 'the white heat of the technological revolution.' In 1957, the Soviet Union renewed its claim on such rhetoric by launching Sputnik, the first artificial satellite. Growing excitement about computerization renewed the same claim a little later. Once again, propaganda inverted reality: Soviet mechanisms of economic control were as if designed to multiply the farces of GIGO ('Garbage In, Garbage Out'). Such was the fog of rival vacuities, that some optimists discerned the 'two systems' as 'converging.'

From the 1920s, support for what was now the Soviet Union meant uncritical acceptance of Moscow's changing definitions of world reality. These depended on power struggles at the top of the new structure. From the late 1920s, Stalin and the more or less fresh bureaucratic caste reacted to economic problems at home and further disappointments (to a varying extent, self-inflicted) in China and elsewhere by forcibly collectivizing agriculture for the swiftest possible industrialization. They presented this as building 'Socialism in One Country.' By now, commitment was irreversibly to the tightest of Lenin's prescriptions for party organization.

The same applied internationally. Foreign policy could confuse billions of people, although before Hiroshima it could not yet kill so many. The Communist International ran as an extension of Soviet foreign policy. Zigzags were the sole

consistent pattern. From 1927 to 1934, all socialists whom the Comintern could not control were treated as 'Left Fascists.' This 'zig' reduced many Communist Parties to sects. Worse, in Germany, it deepened the splits in the labor movement and thus helped bring Hitler to power (January 1933). Even then, change had to wait till 1934, after Vienna's Social Democrats had fought local Fascists physically and after Paris Communists and other antifascists had followed common sense, rather than party leaderships, to fight shoulder to shoulder.

So, from 1934 to 1939, policy 'zagged' toward broad alliance against Fascism. Stalin's foreign policy, however, aimed at allying against Hitler with Britain and France. The latter even had a Communist-supported 'Popular Front' government during 1936–37. But, at its head, the socialist Leon Blum refused to arm Spain's Republic against a clerico-Fascist coup: he feared risking war simultaneously along Rhine and Pyrenean frontiers. This gave a green light to Nazi and Fascist intervention, and made Stalin the Republic's sole supporter. His security apparatus exploited this to the full against any local political rivals, both Spanish and international. Partly as a result of this 'civil war within the Civil War,' the Spanish Fascists won (March 1939), redoubling France's strategic vacillations. The Munich agreement of autumn 1938, reached without officially informing Stalin, had neutralized the sole strategic obstacle near his borders to Hitler. Not surprisingly, he began looking for other allies.

But when he reached a nonaggression pact with Germany, the nature of the Comintern meant that international communists worldwide had to follow: their reality 'zigged.' Of course, once Hitler invaded on 22 June 1941, Stalin woke up from a 3-day panic to find himself in alliance with Britain: Hitler had 'zagged' for him. Little more than 3 years later, Stalin was ordering the two CPs emerging most strongly from the Resistance (the French and Italian) to go easy, while agreeing with Churchill on Soviet domination over Bulgaria and Rumania (where Communists were currently rare and very rare, respectively); Britain would recover control over Greece and would share influence in Yugoslavia '50/50.' Both Greece and Yugoslavia had major resistance movements, more or less Communist led. During 1944–49, the British, later the Americans, helped crush the Greek; in Yugoslavia, the Communist leader Tito was allowed to triumph. In 1948, he broke free of Stalin and, from the 1950s, installed much 'workers' self-management.' But he retained Stalinist structures: transparent in self-deception alone. Although, from the 1950s, he installed much 'workers' self-management,' everything collapsed into nationalism and massacre during the early 1990s.

Dissenters and Mass Murder

Analytically, dissenters from Stalinism had difficulty identifying when things had 'gone wrong.' Trotsky, understandably, emphasized his own defeat in the internal Party battle against Stalin, ending with his expulsion from the USSR in 1929. Till Stalin managed to have him murdered (1940), he expected Stalin's 'betrayal' of the revolution to be reversed, more or less from inside the apparatus. This was increasingly unrealistic, not least given massive purges. From the 1930s, Trotskyists around the globe were excommunicating each other over such questions as whether the Soviet Union was a 'degenerated' or 'bureaucratically deformed workers' state.' From 1944, that dogfight between past participles was even less relevant to countries whose regimes had arrived in Red Army tanks. But, into 1989–91, many Trotskyists in the West seem to have fantasized that a working class in one or more such states would resume the old song from whenever they thought Stalin had interrupted it. They derived hope from popular revolts against Soviet rule: from East Germany (1953) to Novocherkassk (1962), climaxing in the bloody drowning of Hungary's workers' councils (1956–57).

Strategically, Trotskyists suffered from having, all too often, to dispute the same part of the political spectrum as Stalinists. Admittedly, where the latter, true to that 'stageism,' which earlier Marxists had criticized, neglected a colony's working class to concentrate too narrowly on the peasantry, Trotskyists could make some impact in the labor movement. Examples would include Ceylon/Sri Lanka, where the LSSP and organizations derived from it remained important from the 1930s to the 1960s, and Vietnam. In Latin America, *c.*1960 Bolivia would be the leading example. Some of Argentina's were the weirdest, inflating their politics intergalactically to pin hopes on flying saucers from, of course, socialist planets: cargo cultism without contact or Fourier's lemonade.

In spring of 1945, when Vietnam's Trotskyists criticized the Stalinists for initially welcoming British forces to Saigon, the response was massacre. Physical 'liquidation' was already a Stalinist hallmark worldwide against rivals or perceived rivals: Spain had established a pattern. A smaller group of victims would be Polish Trotskyists from 1939: a minor target at coordination meetings of the Gestapo and Stalin's NKVD. In Paris, more than one Trotskyist would be eliminated amid the chaos of Liberation in 1944.

But of course loyal Stalinists in the USSR themselves lived perilously. Mass-murderous paranoia was routine from the early 1930s. A regime that had allowed about 6 million Ukrainians to starve to death for resisting forced collectivization during 1932–33 was also capable of more active measures. Repeatedly, fresh dangers were identified, or dreamed up, for liquidation. As if harmonizing with an officially now 'planned' society, the production of deportees and corpses was centrally decided and, at lower levels, quota driven. West Ukrainian Poles had the doubtful honor of being the first ethnic target, later that decade. Till Stalin's death in 1953, there followed Volga Germans, most Chechens and Crimea Tartars, many Balts, numerous members of other Muslim groups and, from around 1950, Jews. Only that supreme death may have saved the latter from mass deportation. Within overall targets, the sheer chanciness of purging is too forgettable – as when Stalin's last secret police chief, his fellow Georgian Lavrenti Beria, favored one Moscow football club by having some players from its local rival deported. Presumably, this was not why the first decision made by Stalin's other successors was to shoot Beria. Maybe there are similarly sick jokes around the perhaps 45 000 000 victims of Mao's 'Great Leap Forward' (his reworking of Stalin's forced industrialization) or of his ensuing 'Great Proletarian Cultural Revolution.'

Beria's murder soon came to symbolize the end of state terror. But was this enough to make the USSR desirably socialist after all? Not for all socialists. For some, the Kremlin's successive 'liberalizations' and 'thaws' were irrelevant to the system's obvious lack of any vestige of more than ritual control by the majority classes. Victor Serge, even while still inside Russia during the mid-1920s, was perhaps the first to transfer the Fascist (and exsocialist) Mussolini's self-description to Stalin: 'totalitarian.' During ensuing decades, others – e.g., Otto Ruehle, Pannekoek, C.L.R. James, Raya Dunayevskaya, and 'Tony Cliff' – talked of 'state capitalism,' so putting the Soviet regime on some continuum with capitalist societies of the 1940s to the 1980s, evidently closest to the most repressive of these. More writers played with the word 'bureaucracy,' thereby elevating symptom into system.

Other socialists reacted against the Soviet model more superficially. Thus the small British Communist Party lost one-third of its members, workers, as well as intellectuals, under the impact of Hungary and of Krushchev's blaming of everything bad on one man (both, 1956). In many countries, disillusion propelled many into a kaleidoscope, known as the 'New Left.' In Italy, 1956 and the reinvasion of Czechoslovakia in 1968 helped the Communist Party (PCI) become Social Democratic in all but name, at the regional level one of the world's most successful ones. This process was oiled by judicious use of the jottings of the party's founding intellectual, Antonio Gramsci (d. 1937): as he had to smuggle them past a Fascist prison governor, they were serviceably ambiguous.

Ironies of Cold War

But at the national level, even the PCI was excluded from power. This was because, from first to last, Soviet and Western leaders, including many socialists, had seen each other as rivals or enemies. This was played down most during Hitler's invasion of the Soviet Union from 1941 (except in Finland). But, as the Nazis proved even more self-defeatingly brutal than Stalin, that phase proved temporary. True, some individuals such as Armand Hammer, of Occidental Oil and much else, could do big capitalist business with the Kremlin from Lenin to Gorbachev. And political or other prisoners in at least China, East Germany, or North Korea have been used as strike-free labor for foreign firms. But ideologically, rivalry remained the main game.

This had at least six effects. First, people living under one regime tended to swallow the propagandistic self-image of the other. Second, the controllers of each feared such propaganda, thereby enhancing its plausibility. Third, just as imperial rivalries between the British and French Empires had been one precondition for even the bare survival of the (1791–) Haitian revolution, so twentieth-century anticolonial movements in Asia, Africa, and elsewhere could profit from the 'East–West' rivalry. Admittedly, there were also costs, as when Cold War pressures speeded Cuba's initially unorthodox revolution (1959) into the Soviet embrace, or as when the ANC's Eastern-bloc-trained security arm raped, tortured, and killed a number of young volunteers. But, once East–West rivalry ended, Cuba was high and dry, while the ANC had to compromise with those who had benefited from apartheid. It had of course been prepared for this somewhat by Soviet stageist prioritizing of 'national' over 'socialist' struggle against Western colonialisms. Unlike with 1990s South Africa, in 1927 the same logic had allowed China's nationalists to reward Comintern support by massacring communists out of the cities.

Fourth, Cold War merely complicated Western socialists' ambiguities over colonialism. Many members of Britain's 'Labour' Party had long been friendly to India's National Congress. Not so their leaders. True, even these recognized reality by abandoning the subcontinent during 1947. But they continued to see colonies as economically useful for metropolitan Britain, behaving imperialistically toward many anticolonial movements. During 1945–46, such internationalism extended to killing at least 10 000 in Surabaya (Java) alone as part of bringing Dutch colonialists back. French leaders, except during the short-lived premiership of Pierre Mendès France, supported successive bloodbaths in Indochina and Algeria (1945–62); in practice, their Communist competitors were seldom much better, unlike some conscripts and individual socialists. Such traditions boded ill for popular reaction to large-scale immigration from excolonies during and after the 1950s.

Fifth, from 1989 to 1991, the existence of a 'socialist alternative' to Western capitalism sometimes put the latter on its best behavior in matters social, economic and, with, for example, America's civil rights movement, 'racial.' This was partly because, sixth, the Nazis' mistake of 'going too far' had further diminished the attractivity of Fascism as an option for ruling groups in capitalism's heartlands such as Western Europe, although ambiguously in Southern Europe and never elsewhere. Even in 'heartlands,' the United States and Canada saw decades of political blacklisting against anyone seen as remotely deviant. Destruction grew physical when the Federal Bureau of Investigation killed some leading Black Panthers. Internationally, American-instigated crushing of anything remotely egalitarian in Guatemala (1954) and, above all, of Salvador Allende's socialist government in Chile (1973) reaffirmed the rules of ideological engagement, even while providing all wings of the worldwide socialist spectrum with plenty of ammunition for arguing that Allende had gone too far or, alternatively, not far enough. More homegrown reaffirmation had occurred with the erasure of at least half-a-million Indonesian Communists during 1965–66.

Fundamentally, Western socialists' greatest successes in policy and often in party politics came during capitalism's longest-ever boom, from 1945 till at least 1973. Conversely, the interwar depression, like the post-1980s neoliberalization of economy and society, was increasingly negative for socialists everywhere. The main exception strengthens this rule: the inauguration of decades of dominance by Sweden's Social Democrats during the 1930s. This had resulted, notneither merely from homegrown Keynesian economists, nor from the long-term compromise signed between the trade unions and the employers, nor even from a soon exemplary record in welfare-policy, but also from Nazi rearmament boosting demand for iron ore.

At any time, though, socialist leaders might be obliged to prove, at least as obsessively as nonsocialists, their 'fitness to

govern' the existing system. That three of Britain's five post-1945 devaluations of the pound sterling occurred under 'Labour,' underlines how difficult this could be. Finally, four successive lost elections impelled that party in 1995 to ditch even ritual commitment to Clause 4. More consistently than any predecessors, Tony Blair led his adjectivally flexed 'New Labour' into courting the 'center ground.' His adoption of Thatcherite economics was unoriginal: New Zealand's Labor government had preceded him. But his 1997 landslide victory made his airy talk about a 'Third Way' (what between, varied) into a success talisman for a number of socialist leaders. Back in 1959, Germany's SPD had dumped all its Marxism. The *c.*2000 SPD leader, Gerhard Schroeder, now followed Blair, if at increasing distance, in joining a rightward-moving consensus for privatizing the public sector and against many of the poorest, whom the Party had been founded to empower.

Summary and Outlook

Brevity requires abstraction. Roughly during the century from October 1917, socialists concentrated on either clambering out of the wreckage at various speeds (China's leaders the most capitalistically) or making capitalism less capitalist. Each preoccupation undermined itself, the latter all the more obviously now that neoliberalism is acceleratingly marketizing societies, let alone economies. Now that even procapitalist governments feel compelled to talk of international control, they are on socialist terrain. Whether socialists are heard there any more depends partly on how they see manual and, say, computer proletarians allying. Whatever happens, proletarianization itself is surely accelerating.

Abstract

Socialist law as a legal order was a major legal family with common characteristics. The concept of socialist law expresses the ideological legacy of Marxism–Leninism. It was understood by its proponents as the expression of the will of the working class, and an instrument of class struggle, as well as a means for building a communist society. The article examines the extent to which socialist law fits into any concept of law, in light of the facts that its roots were totalitarian and that it had a purely instrumental legitimacy. The authors also introduce the development, structure, and substantive and procedural institutions of socialist law, along with the socialist administration of justice and perception of international law.

Socialist law, as an actual legal order, was a major legal family whose members possessed similar characteristics. The common features of the legal systems of the Soviet Union and communist East-Central Europe resulted from the use of socialist law in maintaining communist party dominance over state and society. Yet the law in the various socialist states differed, too, not only because of modifications in the forms of domination but also because Soviet legal solutions were imposed on diverse cultures and societies.

The ideological legacy of Marxism–Leninism is expressed in the concept of socialist law. According to Marx, law was the will of the ruling class supported by statutory validity.

Socialist law as the positive legal system in communist countries was understood by its proponents as the expression of the will of the working class (or, when class struggle was less emphasized, of the 'toilers'), and it was an instrument of class struggle as well as a tool for building communist society. In the early years of the Bolshevik Revolution, workers' revolutionary legal consciousness was deemed the source of applicable law. Given the totalitarian roots of the legal system, to what extent the norms of the communist state fit into any concept of law remains a fundamental question. If law is a social phenomenon or institution that differs from its environment, is socialist law a law at all?

Stages in the Development of Socialist Law

Socialist law changed over time. It served totalitarian regimes whose efforts were not always successful. State socialism was totalitarian in the sense that it attempted to construct all-embracing state control over every sphere of social life in the service of a single goal. In the early years of the socialist revolution and during certain periods of Stalin's rule, physical control and repression through brute force played the crucial role in this attempt to achieve total social control. In the early phase of socialist legal theory, Pēteris Stuchka emphasized the state power as a "powerful weapon in the hands of the revolution." Stuchka promoted the revolutionary model of socialist legality, which as a continuation of revolution, understands the law not merely historically but dialectically, with a face toward the future. In this sense state power and proletarian dictatorship are essential for the law to develop in an organized manner. It followed that law as a tool of social management, or one that limits government action in accordance with its own specific logic, could not exist. Law was not a serious consideration for the revolutionary mindset. This disregard was facilitated by Marx's belief that there was no place for state and law in the classless society. But Marx also believed that the transition leading to the classless society would be long, and he expected that law, in socialism, would contribute to the extension of equality under the law. Lenin argued for a dictatorship of the proletariat 'based directly upon force and unrestricted by any laws.' In the postrevolutionary period, the communist party position was uncertain regarding the future of law. Yevgeny Pashukanis, the leading authority on communist legal theory, wrote in 1928 that law was a temporary system dictated by commodity relations, and thus the legal superstructure reflects the economic organization of the society. Once socialism had eradicated commodity relations, legal forms would also disappear.

In the 1930s, law (not only criminal law) was structured as an unrestrained authorization, and even a command, to intervene in anything and everything. Such calls to uncircumscribed, coercive intervention transgressed the limits of legal forms. The 1930 joint decree of the Central Executive Committee and the Council of People's Commissars of the USSR, which empowered local authorities to "take all necessary measures … to fight kulaks," would hardly satisfy any definition of law. But legal forms continued to exist even after the planned economy was fully developed. And even during the oppressive Stalinist regime, legal forms were employed at least for show trial and propaganda purposes. Law remained an important internal and external tool of legitimation as exemplified in the Soviet Constitution of 1936 (known as the Stalin Constitution). Law served as a force of total repression in the 1930s, in the sense that it reminded people that they could be brutally handled for no apparent reason and without any protection from other state institutions.

As communist party oppression neared anarchy, unlimited power turned against the elite and their supporters. Totalitarian disregard for the specific needs of the economy and other areas

of social activities drifted into dysfunction. Stalin himself 'brought law back in.' But the promised legal stability had 'nothing to do with the legal restraint on power, and it coincided with the period of greatest repression.' The system moved 'from lawless repression to repressive law' (Krygier, 1994). Officially, socialist law was proclaimed (by socialist leaders) to be the most developed form of law in history, as it served the most developed social formation (communism). It provided socialist legality, a qualitatively superior alternative to bourgeois rule of law. The typical differences between socialist law and bourgeois law, according to socialist lawyers, were the dominantly economic perception and educational function of socialist law as well as its aforementioned underlying purpose, the establishment of communism. From this point of view, bourgeois law is based on a defective capitalist economic system, which by itself precludes the very morality it seeks to create. In addition, because bourgeois law did not rest on the achievement of a grand objective, socialist lawyers considered the efforts of bourgeois law to create order to be a blind endeavor. In reality, however, socialist legality often served show trial and other propaganda purposes only, as exemplified by the Stalin Constitution.

Laws enabled the direct repression of Stalin's Great Terror, although the mass-scale extermination (the purges, the gulag, etc.) was based on action that presupposed a disregard of promulgated legal norms (trial procedure rules, evidence). This is not to claim that the 'disregard' was not officially sanctioned and ordered: disregard of the then-existing official law was a systemic component of the totalitarian use of power. The resulting destruction of social and individual resistance to communist authority, the irrevocable stamp of fear in almost every citizen, served in the remaining half of the twentieth century as the foundation of the repressive order, which could afford to make use of less coercive laws.

After Stalin's death, in 1953 the communist elite reverted to a certain level of legal formalism, by and large for their own protection. This was achieved by a duplication of sorts of the normative system. The legal authorities had strictly observed secret rules regarding actions affecting members of the communist *nomenklatura* (the system of patronage within politics and administration in Communist countries): to proceed against one of its members required authorization from the proper body within the *nomenklatura*. The *nomenklatura* followed its own 'rule of law,' which did not include the right to a hearing of the concerned. The legalistic turn had a certain spillover effect on the rest of the population. Increasingly, law became less directly coercive and punitive and, at least in some of the satellite states, in matters of secondary importance it no longer depended fully on politics. On the other hand, law was recognized as a system that provided structure to a bureaucratic state capable of economic centralization. (The copying of Soviet solutions resulted in less damage to legal forms in the East-Central European states than in the Soviet Union because the use of brute, Stalinist force lasted for shorter periods in these states and because Western legal traditions existed in some of them.)

Beginning in the 1970s, the relative autonomy of law was officially recognized. For reasons of regime legitimation, it was overemphasized to disguise a poorer reality of limited autonomy. Nevertheless, the formal characteristics of modern law (abstractness, general nature of commands, etc.) survived, although in simplified and distorted forms. The instrumental use of law served a bureaucratically ossified institutional politics. The official doctrine emphasized that the autonomy of law could be relative only vis-à-vis the economy, which determined all forms of social life. "Legislation, whether political or civil, never does more than proclaim, express in words, the will of economic relations" (Marx and Engels, 1976). In reality neither the economy nor other social relations were respected, and only specific concerns of power and domination mattered, as understood by the communist leadership. Law remained a tool of the planned economy, and it served the deliberate changes of the planning system.

Law was declared the engineering device that helped organize people in their building of communism. The composition of courts also promoted the educational function of socialist law, for citizens, as people's assessors, could experience the justness of both socialist law and judicial activity through direct participation in the administration of justice. Furthermore, the institution of people's assessors could be regarded as a step taken toward the ultimate disappearance of law. Revolutionary law, although an instrument of class struggle, had an element of internal legitimacy, as it served social (class) justice (through murderous revenge, expropriation, and redistribution). In the instrumental understanding of socialist law, moral considerations became irrelevant. Instrumentalism was also distorted, however, as 'relative autonomy' allowed only very limited respect for the characteristics of the tool. Legal dogmatics or consistency requirements were easily skirted. Yet there were actual elements of independence in law simply because the political system could not generate a unified will. There was competition within the communist political elite, which contributed to at least superficial respect for legal forms. Moreover, law-enforcement organizations had a vested interest in legalism, and to the limited extent that they played a role in party politics, law became a point of consideration. To the extent that the communists needed efficient state machinery, they needed law as an instrument of control over the state bureaucracy (*see* Administration of Justice). Law was important insofar as centralization required uniformity and unity of action.

The Structure of Socialist Law

Socialist law was understood as an ideological superstructure, and its provisions were subject to ideological scrutiny. Law (its provisions and understanding) had to be politically correct, as understood by whatever ideological line the communist party touted. The ideological roots and functions of socialist law led many commentators to the conclusion that it was a mutation of natural law. It was argued that it originated in a set of doctrines or expectations that were above the law. Even the vulgar Marxist claims that law as superstructure reflects economic realities might have been interpreted as being in the natural-law tradition: it was the mystical economy with its 'objective law' that determined law. Socialistic traditions of social justice also show structural elements of natural law. Max Weber criticized these socialistic tendencies to material justice as detrimental to the formal, rational qualities of law.

Socialist legal systems, as they existed in state-socialist regimes, were positivistic and functioned as positive legal orders. According to the prevailing definition, law was the hierarchically structured, sum total of state-made norms. The profound departure from promulgated norms and principles occurred not because of the observance of some kind of higher law. On the contrary, the departure was the result of changing secret orders, commands, and expectations emanating from the communist party leadership and secret services. Of course, once such external political intervention becomes routine or even institutionalized, one can argue that there is no more law in the sense of normative, predictable expectations; hence socialist law (at its worst) does not fit into any notion of law.

Socialist legal systems, in principle, were strictly hierarchic. Statutes (parliamentary enactments) were of absolute supremacy, while constitutions offered only guiding perspective and basic rules of state organization. Law had to originate from the people's representatives; therefore, judicial lawmaking was ruled out as ideologically unacceptable, after the early revolutionary period. Statutes were supreme because they were enacted by parliament, which was held to be the supreme state body. The rigid position on legal origins reflected the dominant nineteenth century German and French views and a simplification of Rousseau. Each socialist regime institutionalized some kind of small and reliable body within parliament (often called a presidium). The presidium had full power to act on behalf of parliament, which convened infrequently. The presidium had the power to amend existing laws. Decrees were subordinated to statutes. In theory, decrees were to serve exclusively for the execution of statutes. But in reality, substantive issues were often determined at the level of executive decrees. Officially courts were restricted to pure application of the law; they could not and did not engage in either judicial lawmaking or the adjustment of existing norms to the prevailing circumstances. Lenin described the socialist court as 'an organ of state power.' Judges were subject to the law and were not allowed to have an indifferent attitude toward the policy of the government. Courts had to endeavor to administer justice in conformity with the directives of the government, bearing in mind the principles of socialism and the socialist sense of justice. However, a number of practical issues were determined by guiding principles of supreme courts on the basis of 'the laws in force.' These guiding principles determined the application of particular enactments or at times filled the gaps in law. *Stare decisis* (the doctrine of precedent) and the binding force of precedent were unknown doctrines in this system; lower courts were, however, bound to follow interpretations of higher courts in the name of socialist legality. This was imperative given the informal control over the judiciary (*see* Administration of Justice).

Substantive and Procedural Institutions

The centralized socialist management of the economy and social life was suspicious of any expression of autonomy. The priority of 'social interests' (or 'society's interests') defined the legal system. No autonomy (in the sense of self-determination) was permitted, and legal structures enabling or protecting autonomy were pruned even from private law. The traditional continental divide between public and private law was refuted as bourgeois legality. As Lenin stressed: "We acknowledge nothing as 'private.' For us *everything* in the province of economics is in the domain of *public law* and not of private law …. Hence our task is … to broaden the right of the state to abrogate 'private' contracts." In practical terms, this meant not only the denial of privacy and sanctity of contract but also the primacy and special protection of state property. The other reason for giving public law prominence was that, as socialist law aimed to create a new social order, any violation of law affected, beyond the actual victim, the state as well as public interests.

Depending on the period, private property and private initiative were prosecuted, prohibited, or greatly restricted, at best. Private ownership was recast as personal ownership in order to allude to the fact that it must only be used for the satisfaction of personal needs and for the purpose for which it was intended, and this property could not be utilized for gaining profit. Property consisting of the 'means of production' was restricted even where it was permitted (as in the German Democratic Republic or, as far as land was concerned, in Poland). 'Social interests,' determined by the state, were favored above all other claims. Restrictions on personal freedom went beyond etatist concerns. Freedom of movement and residence were limited, and at least in the Soviet Union, where the czarist tradition survived, freedom of internal movement was subject to administrative approval.

Speech and press freedoms were permitted only in the interest of workers, which resulted in institutionalized or informal but total censorship. Personal choices and alternatives were limited or prohibited (including choices about education, health, profession, sexual identity, and the like). State control over the individual was extended to the intimate, private sphere. Decisions regarding family relations were subject to intervention by the *Prokuratura* (State Attorney's Office). Abortion was not an issue of self-determination but a matter of demographic or workforce politics, although certain social compromises were observed in this context. In Hungary, the nearly unlimited access to state-funded abortion was the result of an official repudiation of coerced demographic policies. In other countries, like the Soviet Union, abortion as the primary form of family planning derived from a total disregard for human dignity.

The legal restrictions imposed on the general population went hand in hand with the award of privileges for supporters of the regime, although only certain privileges were codified (e.g., access to higher education for family members of committed regime supporters). Privileges were not absolute. They were the reward for loyalty to the system. But the ordinary, loyal citizen (contrary to the *nomenklatura*) had no title or claim to privileges, which, when bestowed, were an act of grace and goodwill. The discretionary distributive powers of the public administration were used to favor the politically loyal (or at least to punish the suspect). This was the case, for instance, in the assignment of public housing. During the less dictatorial periods of state socialism, these discretionary methods of allocating goods and services were the primary tools of social control. Social control through the discretionary application of law put society in a condition of permanent dependence.

Administration of Justice

The contribution of the administration of justice to the restriction of liberty varied historically. During the Stalinist terror, courts served as theaters of repression and injustice. In less dramatic times, the administration of justice promoted etatism and protected the interests of the communist party. Most administrative decisions could not be appealed in court, although in Hungary and Poland, as a rule, there was the possibility of appeal against administrative decisions, except those involving the more sensitive issues of military and police administration.

As to judges, in the formative revolutionary years of socialist power, the legally trained personnel of the previous regime were replaced with incompetent but politically trustworthy laypeople. The basis of revolutionary justice was the revolutionary consciousness of worker-judges. After World War II, in the Soviet-dominated satellite states the 'democratic attitude' of lay assessors played a role in politically charged procedures. In more settled times, judges received formal legal training but worked in personal and organizational dependence on court presidents. Courts were technically under the control of the minister of justice. These courts were not structured to be independent, and the existing political control further increased the likelihood of 'telephone justice.'

Socialist legal theory emphasized the key role of the *Prokuratura* in the administration of justice. The organizational design of the Soviet *Prokuratura* was inherited from the czarist administration. It was a select, centralized body; procurators served in total subordination to their superiors, in what was a quasimilitary organization. They were much better paid than judges. The *Prokuratura* was in charge of criminal prosecution, representing the state in court, but it also routinely supervised the activities of the state administration. Lenin considered the *Prokuratura* the bulwark of socialist legality. He knew that a centralized state power could not afford any particularism, and all local, particular normative systems represented serious deviance. Normative particularism was especially dangerous if it originated in state bodies. As Lenin wrote to Stalin, "legality cannot be legality of Kaluga or the legality of Kazan but must be one single all-Russian legality." Thus the task of the Prokuratura was to "see to the establishment of a truly uniform understanding of legality." The supervisory powers of the *Prokuratura* included the authority to ask for ordinary and extraordinary review of court decisions, even when it was not a party in the case it sought to review. Ironically, the fear of localism resulted in minimal protection for the population: the central bodies had an interest in mobilizing local populations against local authorities, and they encouraged denunciation of local (nonpolitical) abuses to the extent that they deviated from centrally authorized injustice. The dependence of citizens on local services was attenuated in the name of central law. Rules of procedure aimed to protect the material and political interests of the state, and allowed for paternalistic intervention in private litigation. The procedures followed simplified continental models that had traditionally existed in the given country. The inquisitorial nature of the traditional continental criminal procedure was further aggravated by Soviet solutions regarding the admissibility of police-gathered evidence.

In civil matters, judges were required to establish 'objective justice' and were not bound by parties' motions. The paternalistic nature of continental civil procedure dramatically increased, resulting in further dependence, as far as the parties were concerned. On the other hand, the simplifications and limited access to court yielded cheap and relatively swift administration of justice (where courts were available at all). Civil litigation rates were stable, and the most common type of litigation was divorce related. Criminal litigation (except when criminal justice was used as a tool of class struggle, in the 1930s and 1950s) stabilized at a low level. Criminal behavior was limited because of the efficient social control exercised by the oppressive state mechanism.

The perception of the role of advocates was also peculiar, as they had to seek cooperation in the course of their activities with the judge and the prosecutor, and reveal the matter before the court in all its aspects, even at the expense of proving the guilt of their clients. Hence advocates were considered as servants of socialist legality, who contributed to justice and put the interests of society before that of the pleaded individual. In the Soviet Union, the objectiveness of advocates was fostered by a collective organization of advocates. Individuals had to contact such groups of lawyers, which in turn designated their advocate and determined the amount of fee to be paid.

Perception of International Law

A coherent theory on international law cannot be encountered in Marxist ideology. Economic considerations, however, made both the conducting of international trade and the development of international relations inevitable. The gaining of a public law character by socialist law also affected international law. In the wake of the realization that an international trade monopoly existed in socialist states, the state almost always appeared as a subject of treaties concluded with other states or their citizens or legal persons. Public and private international law intertwined, and the regulation of international economic relations became increasingly a matter of public international law. Similarly to domestic law, international law was considered class law. According to certain scholars, such as Evgeny A. Korovin, the international law of socialist states stood in opposition to the international law of bourgeois states. The doctrine of 'internationalist solidarity,' which was followed by socialist states and expressed the necessity of conformity to the Soviet Union, constituted the cornerstone of both the foreign policy making and regional cooperation of these states, and served to put into effect the policy formulated and directed by the Soviet Union.

This separate conception of international law, however, did not reckon with the fact that socialist states and capitalist states cooperated in their economic and other international relations and to maintain and ensure peace. Once the socialist bloc declared the peaceful coexistence of capitalist and socialist states, it had an impact on the development of international law. The principle continued to exist in the form of the principle of duty of states to cooperate, according to which states "have the duty to co-operate with one another, irrespective of the differences in their political, economic and social systems … ." (G.A. Res. 2625, 25 U.N. GAOR Supp. No. 28. (A/5217),

121 (1970)). Although socialist international law recognized the principle of sovereign equality and territorial integrity of states and the prohibition of intervention in the domestic affairs of states, in reality these principles were observed in their breach.

Socialist states generally considered both theories describing the relationship of international law and domestic law – that is, monism and dualism – equally acceptable. However, within the framework of monism they only recognized the primacy of domestic law over international law, and rejected the primacy of international law, claiming that this idea was contrary to the sovereignty of states.

The so-called Brezhnev doctrine, according to which socialist states must take into consideration the dictates of socialism and the fundamental interests of other socialist states in the course of making decisions, was likewise meant to restrict the political independence of members of the socialist bloc. The doctrine sought to reconcile its content with the respect for sovereignty by arguing that the sovereignty of individual socialist states could not be in opposition to the interests of the socialist world or the worldwide revolutionary movement, and as such, the observance of interests of other socialist states could not be labeled as a limitation of sovereignty.

The 'absolutization of sovereignty' (Kovács, 2007) can also be observed in the determination of matters falling in the exclusive domestic jurisdiction, or domaine réservé, of states. Individuals were generally deprived of their citizenship if they emigrated to a bourgeois state, mainly on the basis that they 'gravely violated the requirement of alliance of citizens.' At times the property of such individuals was confiscated in part or in whole, and they were not even allowed to return until the political transition, after which many of them were repatriated. The socialist conception of human rights, furthermore, demonstrates the socialist perception of the relationship of the individual and the state by differentiating human rights from the rights of the citizen, and by overemphasizing the duties of citizens.

In conclusion, although the prevailing definition of socialist law emphasized a hierarchically structured sum total of state-made norms, in reality a fundamental disregard of the promulgated law prevailed. Substantive and procedural institutions like the public prosecutor's office, political control over the courts, denial of access to court, and restrictions on fundamental rights, as well as institutionalized politically biased discretionary powers of the administration, undermined the rule of law.

Socialist Societies: Anthropological Aspects

Abstract

Socialist societies constitute a class of modern societies loosely sharing certain formal similarities in their political, property, and production regimes. They tended toward political monopoly by a Communist Party, a predominance of collective or state property forms, and centrally organized economic production toward redistributive goals. Over time, these formal features were modified by systemic reforms and everyday practices of both citizens and elites, including clientelism, kinship and ritual practices, gift-giving, and other self-forming behaviors. Socialist systems diminished many inequalities yet created new forms of hierarchy.

Socialist (also known as communist) societies constitute a class of modern societies loosely sharing two distinctive features: the political dominance of a revolutionary – usually a Communist – Party, and a property regime resting at first on state or collective/cooperative rather than private property forms, though subsequent reforms sometimes modified those. This definition excludes societies governed by socialist or social-democratic parties in multiparty systems, such as the Scandinavian welfare states. It has historically included, among others, the Soviet Union, the East European countries, the People's Republic of China, Mongolia, North Korea, Vietnam, South Yemen, Cuba, Nicaragua, Ethiopia, and Mozambique. These societies differed significantly from one another – as was apparent in their varied trajectories as socialism decomposed – but nonetheless share elective affinities that justify treating them together.

Socialist societies came into being with the 1917 Bolshevik Revolution and the establishment of the Soviet Union. Others founded later by various means (revolution, conquest, or annexation) all reflected the influence, both negative and positive, of the Soviet model created under Lenin and Stalin. All employed extensive political repression and centralized control, yet they also generally increased living standards as well as access to housing, employment, education, and medical care. Instituting a historic assault on social and gender inequality (see Gal and Kligman, 2000), they improved life chances for many disadvantaged people even while creating new forms of hierarchy.

Research on Socialist Societies

For much of the twentieth century, social-science understanding of these societies was politically circumscribed. Their own scholars were under Party control; nonetheless, invaluable knowledge came from dissidents (e.g., Casals, 1980; Konrád and Szelényi, 1979) and from scholars in countries with strong reform movements (e.g., Kornai, 1980; Wesolowski, 1979). In Western Europe and the United States, scholarship on socialist societies was hampered by impediments to on-site fieldwork and ideologically circumscribed by the concept of totalitarianism, which overstressed the importance of terror and top-down control. This situation improved beginning in the late 1960s, for Eastern Europe and the Soviet Union, as détente and the impetus for technology transfer produced an infrastructure for intellectual exchange and reciprocal influence (e.g., Bockman and Eyal, 2002), and in the 1980s, for China. On-site research led to analyses that discarded the idea of totalitarianism to investigate the inner workings of these societies in more detail, with greater attention to kinship, ritual, gender relations, the mobilization of labor, and the exchange of gifts and favors, as well as more subtle treatments of political economy (e.g., Hershatter, 2011; Hough, 1969; Humphrey, 1983; Walder, 1986; Yan, 1996).

Political Economy and Social Organization

From their beginnings in the nineteenth and early twentieth centuries, communist movements came to power in a variety of ways, sometimes on their own (e.g., Russia, China, Cuba, and Yugoslavia), and sometimes – especially during and after World War II – with the help of external communist parties (e.g., Vietnam, Romania, Hungary, and Poland). Although they varied widely in economic profile (from industrialized Czechoslovakia to agricultural China and Cuba to pastoral Mongolia), all socialist societies embarked on programs of state-led development through central planning that aimed at rapid economic growth by noncapitalist means. The following description begins with 'classic' socialism (see Kornai, 1992), prior to the reforms introduced at various times, and draws on research in both agricultural and industrial settings in China, the Soviet Union, and Eastern Europe.

Redistributive Bureaucracies and Reciprocal Exchanges

Of the three basic modes of exchange posited by Karl Polanyi – reciprocity, redistribution, and markets – socialist systems subordinated the operation of market principles to redistribution, which it made the chief exchange modality and the system's *raison d'être*: everyone would have the right to work, and the wealth they produced would be redistributed as welfare for all. Centralized redistribution required social ownership and control of productive resources, together with centralized appropriation of the product for reallocation along lines set by the Party. To orchestrate production and distribution, Party leaders developed central planning. Fulfilling plans depended

heavily, however, on relations of reciprocity, both clientelistic and egalitarian.

Although these were highly bureaucratized societies, they were not Max Weber's impersonal modern bureaucracies dedicated to procedural rationality. Dense social networks sustained reciprocal exchanges that, far from constituting resistance to bureaucratic control, were intrinsic to its functioning: horizontal exchanges enabled socialist managers to do their jobs, and clientelism facilitated controlling both labor and Party cadres in seemingly noncoercive ways. Personalistic ties extended far beyond the bureaucracy as well, linking ordinary citizens with one another as well as with bureaucrats. The warp and woof of socialist societies, then, consisted of vertical and horizontal relations of loyalty, patronage, and exchanges of goods, favors, and gifts (see, e.g., Ledeneva, 1998). Although the forms of these relations differed according to the various societies' histories and cultures (such as gift relations in China, *compadrazgo* in Cuba or Nicaragua, or specific kinship structures of Soviet minorities), they were widely prevalent everywhere. In every country, words indicating 'connections' (Russian *blat*, Chinese *guanxi*, Romanian *pile*, Hungarian *protekció*, Cuban *compañerismo*, and Polish *znajomości*) often appeared in daily speech.

Organized Shortage

Personal relations were integral to socialism in part because of certain pervasive features of planned economies: tension between Party planners and enterprise managers, bargaining and soft budget constraints, and barter amid shortage. Socialist property was organized in a 'hierarchy of estates' (Humphrey, 1983; Verdery, 2003), within which production occurred by disaggregating the ownership/control rights theoretically held at the center and devolving these downward to the lower level managers, where actual production took place. Because planning could never foresee all contingencies, these managers had considerable discretionary power. Expected to achieve Party directives with inadequate wage funds and to exceed their plan targets with insufficient raw materials, they bore responsibility far greater than the means allotted them for fulfilling it. Therefore, they strove constantly to expand their local power base and their effective capacities. In so doing, they posed a threat to their superiors, who thus were motivated to encourage subordinates' loyalty with favors and patronage.

In redistributive systems governed not by demand for products but by the Party's planned allocation, materials for production could not simply be bought on a market; their availability depended on the supplies budgeted in plans and on often-inefficient central distribution. Managers therefore requested more supplies than they needed, hoping to obtain enough materials to fulfill and exceed their targets: they bargained their plans. Because the planning mechanism required firms to produce regardless of profitability – they operated under soft budget constraints and were rescued rather than bankrupted if they lost money – local managers could overstate their needs for materials and investments and then hoard any excess, with impunity. They also strove to bargain their plan targets downward, making it easier to fill these and have goods left over. Comparable processes occurred in both industry and agriculture, as cadres everywhere manipulated information, underreported production, and engaged in illicit trade to benefit their firm or locale.

The result of bargaining and hoarding was endemic scarcity of the materials necessary for production; thus, classic socialist societies were *economies of shortage* (Kornai, 1980). Shortage caused not just competition among firms but also widespread exchanges, each manager supplying from his hoard today the materials needed by another who would return the favor tomorrow. Thus, firms hoarded materials not only to cover emergencies in their own production but also to backstop the supplies needed by others in their network. These arguments about shortage apply specifically to the process of production, but that process in turn had implications for the availability of consumer goods, generating the queues characteristic of many socialist societies. Although governments encouraged consumer practices, centralized provisioning and poor quality tended to produce alienated consumption, which undermined the governments' legitimacy (Fehérváry, 2013). At the same time, contrary to the prevailing image of socialism as 'wasteful,' limited goods and incomes generated complex systems for reusing and recycling resources (Gille, 2007).

Shortage also affected two other crucial resources: information and labor. Party planners could implement top-down planning only if they had detailed and accurate information. This happened rarely, for lower level cadres had many incentives to falsify information so as to build careers by appearing successful, evade responsibility for disasters, inflate their materials requests, provide cushions against production shortfalls, overfulfill their targets to receive bonuses, etc. From these discrepant needs came a perpetual struggle over information. Higher authorities hoarded it as a source of power and engaged in continual information gathering at all levels of society (Horváth and Szakolczai, 1992). Censorship and close management of information at the top provoked information hunger below, producing a culture of rumor, gossip, selective secrecy, and conspiratorial explanations of events, as well as a citizenry skilled at reading between the lines. Classic socialist societies were thus a special kind of information society (Szakolczai and Horváth, 1991).

Labor Shortage and Rights in People

An additional resource subject to shortage was *labor*. Especially in countries with large peasantries, such as Romania, China, or Vietnam, the absence of a proletariat made it difficult to mobilize skilled industrial workers, and relative economic underdevelopment precluded both attracting labor through high wages and substituting capital-intensive methods. As industrialization proceeded, labor became short in the countryside. Moreover, the shortage economy encouraged firms to employ excess workers so they could complete monthly plans once sufficient materials were on hand (in a frenzied effort known as 'storming'); managers therefore padded their workforce, exacerbating shortage. Labor shortage thus had both macro- and microdimensions. Means for stabilizing the labor supply included making workplaces the locus of benefits such as daycare, housing, vacation permits, pensions, and medical care. Certain cities were closed to immigration, and

construction of urban infrastructures was limited (Szelényi, 1983), thus compelling millions to become village-based 'peasant workers.'

Within each industrial and agricultural workplace, managers had to ensure a labor supply adequate to both normal production and periods of storming. Workers, for their part, might bargain for better conditions by withholding labor, through intentional slowdowns or time off for household tasks and moonlighting. Conflicting demands for labor put a premium on ways of accumulating it through gaining *rights in people*. For managers, these included extending patronage and favors (access to schooling, houses, or building sites), overlooking petty illegalities, and securing loose plans that enabled them to produce a surplus they might use to create labor-securing debt and exchange relations (cf. Humphrey, 1983). Both managers and others needing labor might appeal to kinship idioms, emphasize ethnic similarity, participate in special rituals, and expand networks of reciprocity through gift-giving. Thus, the quest for labor further encouraged personal ties and reinforced particularistic identities.

Second Economies and Socialist Reform

Believing they alone could best determine how social wealth should be redistributed, Party leaders initially opposed economic activity not encompassed within plans. The inability of planning to cover social needs at the given level of technological endowment, however, compelled officials to permit and even legalize some small-scale private effort, known as the 'second' (or informal, unofficial, or shadow) economy. Among its forms were food production on small household plots, after-hours repair work or construction, typing, tutoring, unofficial taxi services, etc. Because these activities overlapped with semilegal and illegal ones, their situation was everywhere precarious, with authorities persecuting them more in some times and places than in others. The second economy was largest in Hungary after 1968, for example, small in Cuba until Castro's 'Rectification' of 1986, harassed in Romania throughout the 1980s; it burgeoned in post-1978 China; extreme forms are reported for the Soviet Union, where entire factories ran illegal production after hours. Crucial to understanding the second economy is that it nearly always utilized materials from the first (or formal, official) economy; therefore, state production units subsidized the second economy's much-touted higher rates of productivity. The prevalence of second-economic activity both indicated popular rejection of the Party's definition of needs and helped to fill those needs by voluntarily lengthening the working day.

Pressure from the second economy was but one of many signs of difficulty in socialist planning that led to repeated efforts at reform, initiated from both within and outside the Party. Beginning with Lenin's New Economic Policy, every socialist society experienced cycles of reform and retrenchment, devolution and recentralization (cf. Skinner and Winckler, 1969; Nee and Stark, 1989). Most exhibited a trend toward less stringent planning and the introduction of market mechanisms, heightened material incentives, and mixed property forms. System-wide experimentation began after Khrushchev's 1956 'Secret Speech,' criticizing Stalin, and increased as each society moved from extensive development (mobilizing resources) to the intensive phase (heightened productivity). Hungary and Yugoslavia introduced the most durable early reforms; those in the Soviet Union ended in the collapse of the Soviet bloc, while comparable reforms continued in China, Vietnam, and Cuba. As they reformed, socialist societies increasingly diverged not only from the Stalinist model but also from one another, introducing path-dependent differences that became ever more marked after 1989/1991, into the twenty-first century.

Despite these differences, the reforms everywhere redefined basic units of activity (revitalizing villages or households, for example, at the expense of collective farms, teams, or brigades); altered gender relations (usually in favor of men and patriarchal authority) and increased other inequalities; affected networks of reciprocity (expanding horizontal over vertical connections); dismantled at least some socialist property forms (as with Hungary's specialist cooperatives and China's decollectivization, begun in 1978); shifted the locus of authority (usually downward, provoking resistance from higher-level bureaucrats); and entailed new, more intimate forms of state control (implied, for example, in Chinese rituals that no longer imagined gods or ancestors as inhabiting a nether world but found them immediately present; see Mueggler, 2001).

Social Engineering and Resistant Personhood

All Communist parties promoted massive projects of social engineering. They accorded a privileged place to knowledge and expertise, which the Party claimed to monopolize. Convinced of the creative power of language, Party leaders both used and modified language in commanding ways that resulted in a standardized authoritative discourse. They spoke of things that had yet to be created – the working class, the proletarian dictatorship, the 'new socialist man' – as if those things already existed, and they developed hieratic speech with reduced vocabularies, clusters of noun phrases, and few (often passive) verbs, creating a limited, static verbal world. Party cadres intervened exhaustively in all facets of life, aspiring to create new moralities and to control populations in myriad ways. They attacked religion as superstition, instituted new socialist rituals, and expanded educational access to create enlightened citizens indifferent to religious belief. They filled the air with moral exhortations aimed at instilling a new, puritan, socialist ethic. Toward better management of resources, they introduced massive population programs, from Romania's enforced pronatalism to China's stringent one-child policy, insinuating themselves into people's most intimate lives to often devastating effect (e.g., Kligman, 1998).

Dedicated to building an alternative to the world of bourgeois capitalism, communist leaders announced an assault on all forms of inequality, including those based in kinship status, gender, class, and ethnonational difference. Society would be homogenized, lineage-based kinship structures broken up, gender differences minimized and authority relations in families altered, classes and private property abolished, national minorities given equal chances. New social entities emerged – state and collective farms, teams, and brigades, for instance – to take the place of kin groups and village structures. When preexisting social relations proved

difficult to abolish, they would be coopted and turned to the Party's purposes (e.g., Kligman and Verdery, 2011). From all these efforts, leaders imagined, a 'new socialist man' would emerge, a new kind of person, along with the 'people as One,' a new kind of human community, bearing an exalted socialist consciousness.

The results of all these interventions were decidedly mixed. To begin with, the Party failed to speak with one voice, as ministries vied for resources rather than cooperating to remold society, and as cadres built their careers by under- or overexecuting central directives and engaging in rampant personalism. In addition, the annexation of preexisting social forms inevitably modified the purposes for which they had been coopted. Exhibiting greater capacity to formulate goals than to implement them, socialist governments were continually plagued by the unforeseen consequences of their policies. To solve conflicts among nationalities, they institutionalized ethnonational difference in ways that served to strengthen it; they embraced nationalist idioms that then overtook socialist ones (Hirsch, 2005; Verdery, 1991). Parties created working classes only to find themselves opposed by their creation, as with the Polish authorities and the Solidarity movement.

Beyond this, resistance to social engineering proliferated even as people adopted the new forms. Constant surveillance politicized behavior: small acts of joke telling became willful anarchy in the eyes of both authorities and joke tellers. Dissidents sought support internally and abroad for their critiques of the system, launching projects to build 'civil society' against the state. Less visibly, peasant refusal to accept starvation from China's Great Leap Forward or Eastern Europe's delivery quotas ultimately forced authorities to renounce these policies (Thaxton, 2008; Rév, 1987), while popular insistence on higher living standards meshed with the parties' own consumption goals to press for reform (Fehérváry, 2013).

Highly complex political effects centered on the making of persons and political subjects. Redistribution and socialist paternalism tended to create subjects disposed to dependency and passive expectation; early campaigns taught the poor to see themselves as victims of oppression (rather than simply of fate) and offered them the Party's instrument of vengeance, in the form of denunciations. Thus, the Party both aroused people's complicity and instilled self-denigration. At the same time, however, many adopted a sort of dual consciousness, in which compliance with socialist forms and values coexisted with the pursuit of one's own independent plans (see Yurchak, 2006). Sometimes but not necessarily conceived as outright resistance, this doubling might accompany a pervasive dichotomization of the world into 'Us' (the people) and 'Them' (the authorities). More significantly, it encouraged subtle forms of self-making in people's own terms: they sought out Western goods, created self-respect through diligent second-economy work while loafing on their formal jobs, participated in ethnic- or kin-based identities and rituals constitutive of self, and gave gifts not just to secure advantage but to confirm their sociality as persons and human beings (see, e.g., Dunn, 2004).

The collapse of Soviet-style regimes complicates a balanced assessment of socialism, which once represented great hope for countless people. Undeniably, socialist societies diminished certain forms of oppression, yet they created others. In many of these societies, an early élan for the expressed goals gave way to cynicism and a feeling of betrayal, as the means used to achieve those goals sabotaged their fulfillment. Admirable gains in education, medical care, and social well-being counted for less against the devastating purges, labor camps, Party-induced famines, environmental degradation, and abuses of human rights. Top-down engineering foundered as socialism's leaders resisted their citizens' efforts to educate them about social relationships, self and human feeling, the value of ritual practices, and the limits to imposed change. The lessons of these citizens' refusals, their silent revolutions from below, should guide future attempts to create alternatives to the world of global capitalism.

Abstract

Although the concept of sociality was championed in the late 1980s as an alternative to 'culture' or 'social relations' as the principal object of anthropological inquiry, confusion often surrounds the term due to a lack of consistency in the way it is deployed. Following recent attempts to rethink the nature of 'the social,' human sociality can be best understood as the dynamic matrix of relations through which persons come into being, and which is navigated by an ethically imaginative and affectively receptive human subject. The challenge facing the discipline is now not only to trace and explain the diverse forms of human sociality but to decide how to incorporate nonhuman socialities into anthropological research and to develop richer accounts of the developmental bases for human intersubjectivity and ethical imagination.

As has long been recognized, human beings are 'social creatures,' whose interactions with each other stand out across the animal kingdom not only for their complexity but also for their sheer variety. It therefore follows that anthropologists, as social scientists who are profoundly concerned with documenting and understanding the ways in which human behavior unfolds in particular settings, should want to ground their inquiries in a theoretical model that can account for why humans exist with others in the world in the specific ways that they do. In other words, anthropology needs a theory of human sociality. To date, however, the concept of 'sociality' has been used in a confusing variety of ways in anthropological writings – a phenomenon that reflects internal disciplinary disagreements over how to theorize 'the social,' as well as the influence of disciplines such as analytic philosophy, developmental psychology, and behavioral ecology, whose established concepts of 'sociality' map incompletely on to the full range of issues with which anthropological research is concerned. Nevertheless, recent efforts to synthesize these different strands of sociality research into a coherent theoretical framework have offered productive new ways of conceptualizing 'sociality,' whilst also raising some difficult questions that the discipline will need to address in the years to come.

The Scope of Sociality

One of the problems confronting anthropologists seeking to engage with the concept of 'sociality' is that it has frequently been defined in ways that are heavily, and inappropriately, circumscribed. A helpful case through which to illustrate this problem is Kaushik Sunder Rajan's discussion of social movements in Mumbai. Taking workers' movements and the collective mobilization of experimental subjects as examples, he suggests that such formations represent moments in which a particular subjectivity (the identification of oneself as a worker, or as an experimental subject) is 'transformed into a sociality' – which is to say it becomes the basis of a shared social identification (Sunder Rajan, 2008: pp. 159, 171). Sociality, in this view, is linked to existence in a (politically motivated) associational community, leading Sunder Rajan to assert that 'sociality cannot be taken for granted – it never already exists but has to be brought into being' (2008: p. 159). Although he has clearly identified an important phenomenon, Sunder Rajan's decision to label it 'sociality' creates confusion for readers who have elsewhere encountered the more widespread anthropological view that sociality is a foundational dimension of the human condition. And it does so with good reason, for on a substantive level, in what sense is a state of shared social identification any more of a 'sociality' than the frustrating, but still highly social, experience of trying to express one's experience to others and yet never being fully understood? What if one were to conceal or suppress one's status as, say, an experimental subject, but nevertheless socially identify with others as a resident of Mumbai, or as a citizen of India? That, by Sunder Rajan's definition would also be 'a sociality.' And so what if, regardless of what other identifications one might make, one recognized (implicitly or explicitly) that one lived in a world shared with fellow beings whom one could identify as similar to oneself – as other humans? Surely that would also be a 'sociality'? Very quickly, we are left with a situation in which the idea of an 'associational community' can be both highly specific and very broad. The challenge this presents is not to draw a line that can decide where the category of 'sociality' begins or ends, but rather to account for how any given human being can participate with others in the world in multiple ways (some circumscribed, and others less so), and very often in multiple ways at the same time.

Sunder Rajanian definitions must therefore fall, but it is revealing to note that similar attempts by anthropologists to define sociality as an observable, bounded, and discrete phenomenon, rather than as an intrinsic feature of human existence, have also tended to equate the term with distinctive features of human life in groups, or with strongly motivated forms of association. Adam Chau (2006: p. 147), for example, has defined sociality as the 'condition of social copresence,' when humans (who may or may not be related or interact) gather in the same social space, such as a cinema or a crowd, while Peter Westoby (2009: p. 2) suggests that sociality is the purposeful and agentive process of creating new social relations, as opposed to the everyday processes of people simply 'relating together.' While such definitional

circumscriptions of the term may admittedly reflect the preoccupations of people who live in the various locations under study, it is concerning that the anthropologists writing about them are so quick to advance these as contributions to the discipline's analytic terminology. Their tendency to do so may partly reflect the influence of the ways in which the term 'sociality' has been deployed within anthropology's cognate disciplines. Behavioral ecologists have typically defined sociality as 'group living,' seeking to excavate the neurological and pheromonal mechanisms that facilitate this, and exploring the evolutionary advantages that such forms of living might convey. Within the discipline of philosophy, meanwhile, several figures have emphasized that although human beings are capable of thinking and acting as individuals – the perspective from which most philosophical arguments begin – it is also possible for them to act from a shared 'we-perspective.' In Raimo Tuomela's *The Philosophy of Sociality*, this 'we-perspective' equates to 'the group's point of view,' an emphasis he defends on the grounds that human beings do not only live but are adapted to living in groups, with the existence of mirror neurons pointing to group conformism as a coevolved psychological disposition (Tuomela, 2007: pp. 1, 240). For Margaret Gilbert (1997: pp. 22–23), 'we-ness' need not involve an entire group – it could simply be the relationship between two people – but it should reflect a sense of 'plural subjecthood' grounded in a specific type of mental connection between persons – that achieved by a joint commitment. Arguing that this is a "distinctive and consequential phenomenon that helps structure the life of all human beings," Gilbert (1997: pp. 17, 29) strongly advocates restricting the scope of the term sociality to such instances of plural subjecthood, fearing that they might be obscured in 'the blur of a broader notion of sociality.'

Prima facie, such definitions can seem appealing, and it is true that all of the authors discussed above have identified intriguing and important phenomena: potential forms and dimensions of human sociality that are worthy of sustained investigation. Such work, however, is unlikely to prove fruitful unless the research is grounded in a broader theory of sociality in the first place. Where group-oriented and plural subject-oriented definitions of sociality of the kind outlined above founder most fundamentally is in their mistaken assumption that sociality is not relevant to those situations in which one is acting as an individual, is not in a group, is not in relation, or is alone. However, such states of being are emergent through sociality, and themselves constitute a form of sociality. As Theodore Schatzki has argued in a discussion of the early Heidegger, to acknowledge that humans are social beings requires acknowledging that human existence is always 'being-with.' In whatever circumstances one finds oneself, there are always others who have a 'bearing' on one's life. Thus "being alone …, far from being an asocial condition, is a way someone who coexists can be, a particular relationship with others. In using a tool, moreover, one coexists with the merchant from whom it was bought, just [as] in opening a gift one coexists with the giver" (Schatzki, 2005: pp. 233–234). From this perspective, phenomena such as the participation in a political movement grounded on the common experience of being an experimental subject, or feeling a thrill in a crowded cinema, or experiencing a mental connection through a joint commitment with a partner, friend, or colleague are all ways in which other people could bear on one's life (and in which one could have a bearing on theirs). However, to crown any of them as quintessential sociality would not only be an arbitrary delimitation of human social experience, it would serve to distract from the many other important (if often less spectacular) ways in which living with others conditions human life. Moreover, it would ignore the fact that one is only ever in situations where one could join a political movement or establish a joint commitment, etc., as a result of previous ways of existing with others in the world. An anthropological theory of sociality thus needs to be able to account for these dramatic and remarkable ways of existing with others in the world, without restricting itself to them.

For these reasons, anthropology is better advised to adopt a broad and encompassing definition of sociality, recognizing it as the dynamic and continually emergent matrix of relations within which subjects are continually interacting and bearing upon each other in a process of coproduction. Such a position was first advanced by Marilyn Strathern and Christina Toren at the 1989 Manchester debate in anthropological theory, on the question of whether the concept of 'society' was theoretically obsolete. Arguing that it was, they instead emphasized the value of seeing the anthropological endeavor as an inquiry into sociality: "the relational matrix which constitutes the life of persons." In this view, humans are continually coming into being through dynamic social processes, rather than being 'socialized' into independent sets of rules, structures, customs, or meanings – and it is the documentation of such processes that is the proper task of anthropology (Strathern et al., 1996). Sociality itself, then, is not a dimension of the human experience divorceable from others. Rather it denotes the state of existence in a dynamic relational matrix, something that is intrinsic to being human.

This more dynamic and processual understanding of anthropology's principal object approach proved appealing to many in the discipline, who were growing increasingly dissatisfied with the static and totalizing notions of 'culture' that lay at the heart of much of the structuralist and interpretivist anthropologies produced during the 1960s, 1970s, and 1980s. It also proved a potent antidote to the emphasis on tracing formal patterns of 'social relations' that had lain at the heart of British structural functionalism for much of the twentieth century. Powerful as this initial formulation was, however, there are several points on which it has needed to be updated in the light of two related theoretical advances made during the 1990s and 2000s (Long and Moore, 2013).

The first is the actor-network theory of Bruno Latour (2007), which has highlighted that it is not just 'persons' or 'humans' that have a bearing upon each other – rather, social life is held together by a whole host of human and nonhuman 'actants.' An illustration of this point comes from the work of sociologist Vikki Bell (2001) in her discussion of the relationships that the children of separated parents have with their nonresident fathers. Although the experiences of the families she discusses are very diverse, in every case the father–child relationship is mediated by the technologies they use to keep in contact, principally the telephone. The fact that a phone can be handed to a child by his or her mother, sometimes accompanied by a wearied announcement of 'it's your

father,' that mobile phones are portable and can be used any time, and that phone calls interrupt the lives of the households they are calling and so need to be timed and spaced appropriately, have a considerable impact on how nonresident fathers conduct relations with their children and their former partners. One of the implications of Bell's analysis is that it is the phones themselves that lead to nonresident fathers becoming a different kind of father, and so we cannot speak of a changing relationship between the humans involved without taking into account the material technologies that mediate the relationship. In this sense, then, the families she discusses are assemblages of both human and nonhuman entities, with the nonhuman also being part of 'the social.' Clearly, this point needs to be incorporated into any definition of sociality, such that the relational matrix it speaks of is not simply one comprised of 'persons' but rather a much more diverse, heterogeneous mix.

A second crucial supplement to earlier formulations of sociality comes from recent discussions of 'affect theory' within cultural studies. These have emphasized that entities do not just bear upon each other through forms of 'social relation.' Phenomena as diverse as the rush of excitement that one can get from being in a crowd, an instant sense of attraction or disgust toward another person, and the state of being 'on edge' that a lone pedestrian may feel in a dangerous neighborhood all reflect the ways in which bodies and environments can transform how humans feel, perceive themselves, and act in the world despite there being no 'relations' to speak of between them. A variety of models have been proposed to account for how these bodily states arise (which range from the postulation of wholly autonomous affects circulating in the world to approaches which ground affective experience in social structures of power and meaning), with no resolution having yet been achieved within the discipline. Despite such ongoing debates, however, it is clear that – whatever their origins – such affective 'bearings' need to be included within contemporary understandings of sociality, rendering the concept yet more expansive in its scope.

However, once the concept has been revised to incorporate recent efforts to 'reassemble' the social, one might reasonably ask whether there is anything more to sociality than noting the mere fact of humans' existence in a relational world, and indeed whether anthropology even needs a concept of 'the social' or of 'sociality.' This is a question on which anthropologists are divided. Those who lean toward dispensing with such categories include Tim Ingold who in 1997 published a searing refutation of what he saw as the prevailing model of 'sociality' within the discipline of anthropology. Characterizing that position as the view that "the basis for society in the strict sense [comes from] the capacity, apparently unique to our species, to render the world meaningful in terms of representations that may be both assembled in the mind and communicated verbally to others," he argued that anthropologists needed to recognize that all human ideas about the world are "fashioned against the background of our active engagement with its diverse human and nonhuman constituents" (Ingold, 1997: p. 232). It thus made no sense, he argued, to privilege some relations as being more 'social' than others. "If some relations are social," he argued, "then all are, and all life would be social life. What need have we, then, for a concept of the social at all?" Of course, once the term 'social' had been abandoned, then the potential analytical utility of a term that means 'being social' – sociality – does not look great.

However, while most contemporary anthropologists would probably agree that Ingold is correct to oppose an exclusively anthropocentric notion of sociality, the recognition that all life is social life does not have to be as trivial as he supposes. If the concept of sociality denotes the state of existence in a dynamic relational matrix, then the simple fact of one's presence in the matrix is only one aspect of what is at stake in the term. The other half, neglected by Ingold, concerns the character of that existence, the ways in which entities behave within, and toward, the matrix of relations in which they are emplaced. In other words, although Latourian and Ingoldian interventions have made it possible to recognize all entities in the world as being social, and thus as embroiled in sociality, this does not mean that they all have the same socialities. The current challenge for anthropology is thus to identify what (if anything) is distinctive about the sociality of human beings, as well as to work out how the socialities of other entities with which human beings interact might be properly accounted for within anthropological analysis.

The Character of Human Sociality

Close your eyes and imagine a crowd of zombies. What do you see? As Shaka McGlotten (2011: p. 187) has argued, zombies are "frequently imagined together as a mass, a crowd, or a swarm, yet they remain alone even among others … . Their sociality differs in that they do not possess the reflective self-awareness or empathetic identification we take as the hallmarks of meaningful intimate connection with yourself and others. This … is part of what makes them inhuman."

These remarks offer some suggestive initial entry points for a discussion as to what might be distinctive about human sociality. This distinctiveness can partly be sketched in terms of the remarkable communicative and interactional capacities or abilities with which humans are endowed: capacities that certainly shape the character of human sociality but, as I shall explain shortly (and *contra* certain widely peddled definitions of 'sociality' as the 'capacity to be social') are not the sum total of it. The ability that is most highly developed in humans (but not in zombies) is intersubjectivity – something that lies at the heart of the process of human–human interaction. Although the term 'intersubjectivity' has, like sociality, been defined in a variety of ways, Alessandro Duranti (2010: p. 10) offers a particularly eloquent assessment of how the term might be understood within the anthropological project, suggesting that it represents the forms of awareness that one might have of "others who see the world, nature included, from their standpoint but, by manifesting behaviors that resemble our own, contribute to the making of one objective – shared or sharable – world possible." Particularly, appealing about Duranti's exposition of the concept is its recognition that intersubjectivity is a condition of possibility out of which many different potential 'worlds' might be emergent. As such, one of the most exciting and distinctive aspects of human interaction is its fundamentally open-ended and ever-emergent quality.

The possibility of intersubjectivity rests upon interactants having a 'theory of mind,' which allows them to attribute

beliefs, intentions, motivations, and even false beliefs to the people they are interacting with, such that they can then behave accordingly. This equips humans with a remarkable range of interactional possibilities, because it allows us to establish channels of communication with any human who also possesses a theory of mind, regardless of their lack of shared language, culture, or history. The processes by which such a theory of mind is acquired by humans, however, are still in the process of being fully delineated. Experimental evidence suggests that although even very young infants of around 12 months in age are capable of taking others' beliefs and intentions into account when acting, more complex aspects of theory of mind – such as the ability to recognize that an interlocutor might be acting under the influence of a belief that one knows to be false – are unlikely to emerge in children under the age of four years. What the precise developmental steps are, and how universally they are followed, remain frontiers of research.

In the absence of conclusive evidence, a number of theories have been advanced to account for how human capacities for interaction arise. The most fundamental point of disagreement is at what level these capacities are emergent and/or manipulable. One possibility, advanced by Enfield and Levinson (2006) is that humans are biologically endowed with an 'interaction engine' that incorporates theory of mind capabilities, biological constraints, and ethological proclivities (such as the mechanisms for conversational turn-taking or the correcting of errors and misunderstandings) and which is then 'fine-tuned' to a local cultural frame through the interactional matrix in which human development actually occurs. This view finds some support in the fact that even very young babies appear to participate in cooperative behavior (an apparent 'instinct' for cooperation) and in regularities of conversational dynamics across diverse settings, which supports the idea that they may have an ethological base (Schegloff, 2006).

Others are suspicious of such a view. Quite aside from the objection that the makeup of any given human's psychology and proclivities is always-already determined by interactional matrices – not least the one which led to their conception (Toren, 2012) – the fixed character of an 'interaction engine' seems at odds with the general behavioral flexibility that humans exhibit in most other areas of their lives. By that logic, one would expect the interactional matrix in which the child grows up to be the more significant factor for their capacities for interaction. Certainly, many sociocultural anthropologists would be naturally drawn toward the possibility that contextually variable representations of 'the mind' could have a significant effect on mental experience, and on the theories of mind that individuals hold (Astuti, 2012). Such a position, however, raises the question of why it is that despite widely differing practices in child-rearing, developmental outcomes appear to be largely the same across children around the world (Gaskins, 2006). One possibility is that the threshold for a 'typical' developmental outcome is set sufficiently low that the exposure to diverse experiences can allow broadly similar interactional capacities to develop in different settings. Another possibility is that the similarity of developmental trajectories has been overstated by researchers who have largely confined their work to occidental settings and/or whose methodologies have led them to overlook subtle but important variations in children's interactional skills.

What is beyond doubt, however, is that certain aspects of the interactional matrix can be definitive factors in determining people's capacities for social behavior. One of the most significant of these is exposure to language, and in particular linguistic terms related to theory of mind, such as the verbs 'to think' and 'to know.' The potential developmental role of language has been explored through a large number of studies with deaf people, including those who were only introduced to sign language in adulthood. Although current evidence suggests that deaf individuals do possess a theory of mind regardless of their degree of exposure to language, late language learners experience persistent difficulties with either reasoning about or expressing an understanding of the nature of ignorance, deception, and false beliefs in ways that threaten to foreclose certain possibilities for interaction (Morgan and Kegl, 2006).

Conversely, while individuals with autism were once (and sometimes still are) seen as quintessential examples of an 'asocial' state of human being, recent anthropological writings have recast autistic people's possibilities for social coordination as being promoted and impeded by the sociocultural ecologies they inhabit rather than as wholly determined by the neurological 'impairments' that seem to prevent them from developing a typical theory of mind. Thus, Ochs and Solomon (2010) suggest that one of the primary challenges for autistic people in establishing social relationships with others is a mismatch in their repertoires of social coordination. While nonautistic humans routinely interact face-to-face, this can lead to an experience of sensory overload for severely autistic children and prove less facilitative of social interaction than sitting side by side. Similarly, a slow, affect-laden 'baby talk' register of the kind commonly used to interact with small children appears to be counterproductive for autistic children, who respond better to moderately paced speech and restrained affect. In a separate paper, Solomon (2012) has explored how interactions with therapy dogs can be used to 'unlock' autistic children's capacities to play and become responsive social beings. Objects and activities from therapy sessions with the dogs (such as throwing a tennis ball) are then incorporated into other settings such as home and school, in the hope that this may facilitate responsiveness to and with other humans. What all these examples point to that it is the dynamic relational matrices in which autistic individuals are placed, and not just their neurology, that delimit the opportunities for social coordination available to them at any moment in time and going forward into the future.

This example from the anthropology of autism also serves to highlight a more general feature of human sociality, namely that dynamic matrices of relations can be subject to conceptualization, scrutiny, evaluation, and transformation by the very subjects who are involved in it. When parents and therapists (and anthropologists) attempt to understand the nature of autism and change the way they relate to the autistic children in their lives, they are doing so with a deliberate goal: to change the matrix of relations in which they are embedded, and to do so for the better. The ethnographic record is replete with accounts of similar endeavors, such as the creation of intentional communities or the instigation of revolutions. That is

not to say, however, that a matrix of relations always has to be transformed. Subjects might feel equally compelled to preserve or maintain it. But in each case, the trajectory that the relational matrix takes is determined by those embedded within it, through acts of what Henrietta Moore (2011: p. 16) has termed 'cultural invention.' What is significant about this observation is not merely the fact that sociality is capable of changing over time, but rather the possibility that it, and the impulses underpinning it, might be at least partly amenable to control.

The capacity for cultural invention is one of the most distinctive aspects of how humans inhabit matrices of relations. As far as we are aware, no other animal (and certainly no zombie) has the capacity to reflect in a sustained manner on their position in the world, to imagine a better way of being, and to then strive to implement it. The remarkable cognitive abilities that human beings possess, including their capacities for virtuality and imagination and their behavioral plasticity – all features associated with being biologically cultural – lie at the heart of this striking feature of human sociality. And yet there are several aspects of the process of cultural invention that warrant further explanation. The first is that we are 'culturally inventing' all of the time. This does not mean we are always busy planning how we will implement our visions of the good life. But every act we take – from deciding to phone a friend on a whim, or declining to strike up conversation with a stranger in a library, shapes the matrix of relations we inhabit. Moreover, it is precisely the fact that most of these choices are not planned or consciously thought-through but rather seem impulsive or instinctive that makes them so worthy of attention. This suggests that anthropological understandings of human sociality need to incorporate three distinct features. The first is the full extent of the dynamic matrix in which any given human being must of necessity inhere. The second is what has sometimes been glossed as 'the human capacity for social behavior' – but which might more precisely be understood in terms of the possibilities for and constraints upon social coordination that are afforded by both the biological makeup of particular humans (a point which includes species-level features and individual developmental trajectories) and the sociocultural ecologies they inhabit. To those, we now need to add a third dimension – one which can account for how a person's capacities to act within a particular matrix are deployed over their lifecourse. As Henrietta Moore and I have argued elsewhere (Long and Moore, 2013: p. 11), this requires a sophisticated account of agency, motivation, intentionality, and desire: in short, an understanding of the human subject as he or she exists in a given place and time, and more specifically *the ethical imagination*: "the forms and means … through which individuals imagine relationships to themselves and to others" (Moore, 2011: p. 16).

One of the reasons that Moore's conception of the ethical imagination proves particularly helpful for thinking about the character of human sociality is that it brings together diverse ways of thinking about what motivates the human subject, recognizing that all of them might have a role to play in accounting for how people navigate the relational matrices in which they are emplaced. Conscious reflective ethical practice of the kind attended to by Michel Foucault is clearly an important part of ethically imaginative endeavor – but so are the forms of identification and desire that proceed through fantasy, or through affective, embodied experiences. Subjects are not only motivated by their own perceptions of what is ethical, but also by fantasized imaginations of distant others, and of the kinds of person that they themselves will become when in relation with such others – as seen, for example, in the desire for 'Western' styles, goods, and partners in many parts of the non-Western world. Equally, practices of relating might be underpinned by more affective, embodied compulsions, as in McGlotten's (2011: p. 189) analysis of gay Americans who explained that they logged on to online cruising sites in order to experience 'a connection to the world' and thereby avoid 'feeling dead.' As these examples show, none of the components of the ethical imagination is free from the influence of broader social imaginaries, and so the ways in which sociality is navigated by particular humans will always reflect their historicity as a product of a long history of social relations in their past. Moreover, while every human being might be capable of ethical imagination, the capacity to act upon this is clearly unequally distributed, with some people in a dynamic matrix of relations being in a much stronger position to determine the conditions of possibility for others than vice versa. And since both ethical reasoning and fantasmic identifications can be profoundly affective, the question of how various dimensions of the ethical imagination interrelate remains a vibrant area of research. Nevertheless, and despite the wave of recent proclamations that anthropology has entered the era of the 'posthuman,' it appears that attending to the very distinctive qualities of *anthropos* and of human sociality will still be crucial for understanding the ways in which heterogeneous networks of entities are inhabited and navigated.

Pressing Agendas for Sociality Research in the Years to Come

Although the alleged distinctiveness of human–human interaction has been the topic attracting most attention from anthropologists concerned with sociality, the recognition that humans are always embedded in heterogeneous networks replete with nonhuman others has started to raise anthropological interest in the character of nonhuman socialities. For example, as Susanne Küchler (2013) has argued, recent innovations within materials science, notably the development of 'responsive' and 'intelligent' materials (such as self-cleaning glass, or containers that monitor the freshness of food) have made the socialities of materials increasingly complex and worthy of investigation in their own right, since the decentered cognition incorporated into their design gives them a capacity to recast and even navigate the networks of relations into which they are incorporated. However, although a growing body of anthropological work is taking note of materials in their specificity, the most vibrant current area of debate surrounds the question of how nonhuman animals interact with each other and with the humans in their lives.

The concept of affect – one of the central dimensions of Moore's conception of the ethical imagination – has proven particularly alluring for thinking about such relations. As noted above, affect points not to an interiorized emotional state but rather to a bodily state; a felt intensity. The significance of this is

that unlike the category of 'emotions,' which presupposes a certain and very human model of subjectivity and consciousness, the only prerequisite for experiencing affective states is a certain degree of sentience (the threshold of which, however, remains open to debate). This means that surges of affect can be shared by humans and nonhumans, affording the possibility of a form of intersubjectivity (or interaffectivity, if you will) that crosses species borders. As Rheana Parreñas (2012) has argued in a provocative recent ethnography of an orangutan rehabilitation center in Borneo, the affect of interspecies encounters might play a crucial role in shaping both human and nonhuman subjectivities. Yet as this self-same ethnography illustrates, salient differences across the species boundary remain. Human keepers are expected to be sensitive to the possibilities of affect, anticipating them and regulating them so as to keep orangutans 'wild.' This very injunction serves to illustrate the key difference between human and orangutan sociality: whilst humans are capable of virtuality, of planning and transforming the affectively laden relational matrices in which they act, orangutans are at the mercy of affect: as Parreñas (2012: p. 678) herself asks, "how can the orangutan not help but be enculturated by the affect produced in the copresence of humans?"

A good question, and one which reveals the depths of the challenges facing researchers currently striving to develop a multispecies anthropology sensitive to the often complex ways in which nonhumans navigate relational matrices of which humans are a part. For despite recent injunctions to engage with the 'alterworlds' of nonhuman species (Kirksey and Helmreich, 2010: p. 553), it remains very unclear quite how this could be done. Behavioral ethology offers points of departure for understanding the 'instincts' underpinning various forms of animal behavior, but remains oblivious to the forms of affective charge that anthropologists such as Parreñas are finding so analytically productive. This raises the question of whether anthropological theories of affect needs to be inserted into behavioral ecology, whether the capacity for experiencing affective surges might only be limited to (or highly developed within) certain species – for example, higher primates, or species that have been selectively bred to serve as companions to humans– or whether 'affect' is in fact only ever experienced by the human in the encounter, and denotes a distinctively human way of experiencing and acting in the world.

Finally, although the character of nonhuman sociality offers an intriguing and perhaps tantalizingly 'exotic' new frontier in anthropological inquiry, much about the character of human sociality remains unknown to us, including the precise developmental mechanisms that afford and foreclose possibilities for interaction, and the origins of the often complex desires and motivations that prompt us to manipulate our matrices of relations in particular ways. While decades of anthropological research has heightened our attention to the ways in which human behaviors and goals might be influenced by political and economic circumstances in which they exist, the precise psychodynamics that underpin such transformations remain open to more detailed investigation. Furthermore, new studies in the emerging subfield of the 'anthropology of precarious life' (Dave, 2012; Wool, 2012) are confronting us with the question of whether certain existential predicaments such as life in abject poverty, or recovery from shattering trauma, might engender distinctive registers of ethical imagination – such as those based on fleeting affections, rather than belief in durable attachments – and so point to important environmental influences on the character of sociality well into adulthood that warrant further theoretical excavation.

It is thus clear that much anthropological research into sociality remains to be done. The principal accomplishment of the past few decades has been to establish the relevance of a concept of 'sociality' – an ongoing, dynamic, and coconstitutive matrix of relations within which persons are forever in a state of becoming – as the relevant object of anthropological inquiry, displacing more its static predecessors such as the concept of 'cultural-' or structural functionalist models of norm-governed 'social relations.' Theoretical developments within anthropology and cognate disciplines such as the sociology of science and cultural studies have helped to demonstrate both the scope and the foundationality of the concept. The priority for anthropologists in the years ahead will be to collaborate with colleagues in related disciplines ranging from psychoanalysis and developmental psychology to behavioral ecology and materials science to understand in more detail the precise mechanisms by which humans and nonhumans alike come to navigate the relations that they share with others and thereby contribute to the maintenance or transformation of the forms of sociality that saturate our world.

Socialization and Education: Theoretical Perspectives

Klaus A Schneewind, Ludwig-Maximilians-University Munich, Munich, Germany

© 2015 Elsevier Ltd. All rights reserved.

Abstract

In this article, first, four perspectives in studying the processes of socialization and education, that is, chronological, topical, institutional, and cultural points of view, are briefly addressed. Then, three major groups of theories, namely biological theories (sociobiology and evolutionary psychology), psychological theories (psychoanalytic, attachment, epigenetic, and learning theories), and sociological theories (structural functionalism, symbolic interactionism, and conflict theories), are described in greater detail. Finally, an integrative framework for studying socialization and education is offered based on five aspects: units of environmental influence, characteristics of individuals, proximal processes, goals and values, and self-socialization.

Socialization refers to all processes by which an individual learns the ways, ideas, beliefs, values, and norms of his particular culture and adapts them as part of his own personality in order to function in his given culture. Education, on the other hand, deals explicitly with intentional attempts at influencing an individual's developmental course. In the following, some core anthropological assumptions guiding the thinking and theorizing about socialization and education are described. Second, major units of analysis, in particular phases of individual development, topics of socialization, socializing institutions, and cultural variations, are briefly addressed. Third, an overview of three groups of theoretical approaches to socialization and educational processes, that is, biological, psychological, and sociological theories, is presented. Finally, some elements of an integrative theoretical framework for studying socialization and educational processes are outlined.

Core Anthropological Assumptions

At the heart of all theorizing about socialization and education are central prototheoretical beliefs concerning the nature and development of human beings. In fact, as Montada (2008) has pointed out, there are at least four distinguishable models of individual development depending on whether the individual and/or his environment are conceived of as playing an active or passive part. Besides endogenistic, exogenistic, and self-creation theories exists a fourth group of theories that views both person and environment as active agents.

The latter group of theories rests on the common assumption that individual development is a dynamic interactional process that evolves in a sequence of reciprocally patterned person–environment transactions. Besides this basic assumption, there are at least six additional aspects that are central to a transactional conceptualization of human development, namely (1) learning capacity, (2) social dependence, (3) experience formation, (4) internal representations of experiences, (5) action competence, and (6) freedom of choice. Action competence and freedom of choice, in particular, are indispensable prerequisites for innovation and change concerning individual and sociocultural conditions of life.

Perspectives in Studying Socialization and Education

When looking at socialization and educational processes from an empirical point of view there are at least four different, albeit interrelated, approaches that can be distinguished, that is, a chronological, topical, institutional, and cultural approach.

In a *chronological perspective*, the course of individual development can be divided in different age-graded phases such as infancy, childhood, adolescence, and early, middle, and late adulthood. The sequence of phases and corresponding transitions is structured by individual developmental tasks (Havighurst, 1953) that, on the one hand, are based on physical and social cognitive maturation and, on the other, on normative expectations prevalent in a given society.

From a *topical perspective*, socialization processes have a strong impact on certain life domains such as (1) physical growth and health; (2) cognitive, social, moral, and spiritual development; (3) sex and gender differences; and (4) self and personality development.

From the vantage point of *institutions*, socialization takes place in different settings that, in some instances, are especially designed to advance the development of a broad spectrum of individual dispositions and competencies, either by formal or informal learning processes, that is, families, schools, peer groups, work settings, and so on.

Finally, from a *cultural* point of view, an individual's development depends a great deal on the values and beliefs that are typical of the culture to which he or she belongs. It has been shown, for example, that the prevalence of an independent-autonomous conception of the self within individualistic cultures versus an interdependent-relational self within collectivistic cultures is closely related to distinct socialization goals and practices stressing either autonomy or relatedness (Triandis, 1995).

Major Theoretical Approaches to Socialization and Education

Although in the present context it is not possible to give a full account of the vast array of theories dealing with the structural and dynamic aspects of socialization and education, three

major classes of theories, that is, biological, psychological, and sociological, are briefly reviewed (see the handbook edited by Grusec and Hastings, 2007, for detailed information).

Biological Theories

Sociobiology and Evolutionary Psychology

Based on Darwin's groundbreaking ideas concerning the phylogenetic evolution of the species, sociobiology and, somewhat later, evolutionary psychology contended that ultimate explanations of human behavior must take into account the superior goals of securing and expanding the successful reproduction of the human species. Especially mate selection and parental investment have been associated with universally evolved psychological mechanisms that are rooted in the human genotype as a consequence of phylogenetic adaptation (Johns and Belsky, 2008). For example, Belsky et al. (1991) have proposed and also presented some research evidence for an evolutionary theory of socialization relating different kinds of reproductive strategies to specific childhood experiences, which in turn entail specific outcomes of an individual's psychological and somatic development. More specifically, these authors argue for two distinct developmental pathways of reproductive strategy. One is characterized by stressful contextual and rearing environments, insecure attachments, early pubertal development, and onset of sexual activity within the context of short-term, unstable pair bonds, which in turn predispose to higher fertility rates and limited parental investment. In contrast, the other developmental trajectory shows the opposite pattern of rearing conditions and interpersonal relationships.

Behavior Genetics

While evolutionary theories focus on universal adaptive strategies, behavior genetic theories concentrate on explaining the variability of individual differences that can be accounted for by genetic and/or environmental influences (Plomin et al., 2008). Behavior geneticists, in particular, have shown that individual differences in cognitive and socioemotional dispositions are not only substantially influenced by the individuals' genotype but also by genetic components of the environment (e.g., via the parents' genotype impacting on their children's environment). Moreover, besides the conceptually and empirically useful distinction between shared and non shared environments, various kinds of genotype–environment covariation and interaction have been distinguished to account for genetically informed processes of individual development. In this vein, empirical analyses of cross-sectional and longitudinal data have led some authors to challenge the environmentalist position according to which, for example, familial influences such as parenting style or family climate have a strong impact on the development of individual differences in the filial generation (Moffitt and Caspi, 2007).

Psychological Theories

There is a wide range of psychological theories that have been applied to describing, explaining, and controlling socialization and educational processes. In fact, all theories dealing with personality and social development have much to contribute to this goal. In the following, four theoretical approaches are briefly described with a special emphasis on the processes of socialization and education.

Psychoanalytic Theories

In classical Freudian psychoanalytic theory the operation of defense mechanisms such as identification or sublimation plays a central role in socializing the growing individual's initially untamed libidinal and aggressive drives. Especially, coping with the oedipal situation via identification with the aggressor is supposed to be a developmental milestone, because it allows the young boy or girl to enormously expand his or her learning experiences, thus leading to a gradually more realistic and differentiated satisfaction of formerly more primitive expressions of his or her drive impulses. Later on, sublimation is the most elaborate and mature defense mechanism, which provides the individual with new ways in his private or professional life to follow through with his otherwise unsatisfied libidinal and aggressive needs at a socially acceptable level.

Fixation is another important psychoanalytic concept that has been invoked to explain character formation at different stages of an individual's psychosexual development, depending on either a lack, inconsistency, or abundance of gratifications at a particular developmental stage. Thus, distinct patterns of socialization practices at different psychosexual stages have been related to particular outcomes of children's personality development. Cultural anthropologists, in particular, have followed this line of reasoning in contrasting more lenient versus strict socialization practices in various cultures to demonstrate, albeit with only partial success, their impact on character formation (e.g., Whiting and Child, 1953).

While the classical Freudian psychoanalytic model is based on the transformation of primitive into more differentiated ways of need satisfaction, neoanalytic theories, especially object relations theories, approach the issue of socialization and personality development quite differently. In object relations theories the central dynamic principle is a person's need for interpersonal relatedness (Greenberg and Mitchell, 1983). In a developmental perspective, the individual acquires internal representations of the self, the other, and the relationship between self and other, which tend to become more and more differentiated. Thus, the quality of relationships that an individual is engaged in appears to be vitally important with respect to his internal representations of self and other (Kernberg, 1984). Empirical studies, however, are scarce and have mostly been limited to the pathology of object relations.

Attachment Theory

Although object relations theories bear some resemblance to attachment theory, the empirical status of the latter is much more elaborated. Attachment theory that combines concepts drawn from ethology, psychoanalysis, cognitive psychology, and systems theory has sparked off a multitude of theoretical, methodological, and empirical refinements (Cassidy and Shaver, 2008). Of particular importance is the discovery of various attachment types (i.e., secure, resistant, avoidant, and disorganized/disoriented attachment in infancy; secure, preoccupied, anxious, and dismissing attachment in adulthood) and corresponding internal working models. Moreover,

it has been shown that specific aspects of socialization are related to different attachment types in theoretically meaningful ways. For example, several aspects of caregiving that promote secure mother–infant attachments have been found. These include characteristics such as sensitivity, positive attitude, synchrony, mutuality, support, and stimulation. Similarly, a number of distinct interpersonal behaviors such as mutual need for intimacy, exchange of positive affect, and constructive conflict resolution have been observed in adult relationships belonging to the secure type.

Epigenetic theories

The common feature of epigenetic theories is that individual development is conceived as a sequence of qualitatively distinct phases concerning the structure of experience and behavior. A prominent example is Piaget's (1954) theory of cognitive development, comprising four major periods from the sensorimotor period to that of formal operations. These are associated with specific cognitive schemes that are built on the interplay of assimilation and accommodation processes. The epigenetic principle has influenced a series of theoretical conceptualizations concerning other developmental domains including moral reasoning, distributive justice, social perspective taking, or ego development (e.g., Erikson's 1950 psychosocial stages of development). While Piaget emphasized the epigenetic sequence of development as an inherent process of self-creation, Vygotsky (1978) put a stronger emphasis on the cultural influences on development. In particular, his concept of the zone of proximal development clearly stresses the importance of socialization and education in the progression of epigenetically patterned levels of development.

Learning Theories

This class of theories covers a wide range of theoretical approaches spanning from orthodox behaviorism characteristic of Watson and Skinner to social–cognitive and action–theoretic conceptualizations of learning. Although the principles of classical and operant conditioning are by no means outdated, the so-called cognitive revolution in psychology led to a paradigmatic shift in learning theories. One of the earliest contributions to this new type of theories was Rotter's (1972) social learning theory of personality which combines basic principles of learning within an expectancy-value framework. In particular, Rotter's concept of generalized expectancies for internal versus external control of reinforcement and the social conditions shaping these expectancies, especially within the family and in the school, stimulated a tremendous amount of research, presumably because of the affinity of this construct to other socially relevant concepts such as autonomy, personal control, helplessness, or alienation stemming from quite different theoretical positions.

More recently, and in a similar vein, Bandura's (2008) social cognitive learning theory of personality comprising – based on his model of triadic reciprocative relation between intrapersonal and environmental determinants – an agentic theory of the self has contributed much to the analysis and theory-guided application of specific procedures fostering the development of the self system by socialization and self-directed action. Besides his influential theorizing and research on the processes of observational learning and modeling, Bandura has focused on the construct of self-efficacy, that is, an individual's belief that he or she possesses the necessary competencies to attain specific goals. In addition, Bandura has shown that the concept of self-efficacy can also be extended to collective efficacy beliefs of groups or even societies.

Sociological Theories

Not unlike psychological theories there exist quite a few theoretical approaches that have been created within sociology to account for the processes of socialization and education. In the following, three are briefly described because of their historical and contemporary importance.

Structural Functionalism

The theory of structural functionalism is closely associated with the work of Talcott Parsons. The main question that Parsons addresses in his theory refers to processes of how individuals become members of a given society in order to guarantee the survival and maintenance of the social system (cf Parsons and Bales, 1955). According to Parsons, society is a global social system that is based on an integrated value system. The individual person participates in the social system by interacting with others in accordance with the various roles and positions he or she holds in that system. The global social system itself consists of hierarchically ordered subsystems that are characterized by corresponding institutionalized norms. On the one hand, these norms are supposed to be congruent with society's integrated value system and, on the other hand, they determine the expectations and rules attached to specific positions and roles. These are further specified with respect to a set of pattern variables comprising, for example, particularistic versus universalistic values. In this respect, the family plays a particularly salient role (Parsons and Bales, 1955). Drawing heavily on Freudian psychoanalytic theory, Parsons contends that via identification with their same-sex parents boys and girls become socialized into specific male and female role patterns. More precisely, gender-related role specialization is characterized by instrumental or task-oriented roles for males and expressive or person-oriented roles for females. Again, these gender-specific complementary roles are supposed to maintain the equilibrium of the family system as well as the social system as a whole.

Symbolic Interactionism

While Parsons' theory of structural functionalism focused on the conditions ensuring the conservation and stability of the social system, symbolic interactionism called into question whether the expectations and behaviors associated with the enactment of roles can be determined as precisely as Parsons suggested. Instead, Mead (1934), who is credited as the originator of the symbolic interaction framework, maintained that social roles are acquired by imparting and sharing the meaning of symbol systems, particularly that provided by language, in order to ensure an appropriate coordination of the actions of two or more interacting persons. The central vehicle by which this can be achieved is the process of communication which makes role taking a necessary prerequisite. In essence, the shared meaning of symbols is a co-constructive process which is an outgrowth of interpersonal communication. Therefore, the notion of socialization is crucial in symbolic interactionism although Mead

himself never used this term. Instead, he talked about the 'importation' of social symbols into a person's mind. For the developing child, the process of importation is marked by two stages, that is, a play and a game stage. In the play stage, the child is an actor with his own needs and interpretation of the situation (which in Mead's terms represents the self as subject or 'I'); while in the game stage, the child is an actor who is confronted with the needs and social expectations of other actors (which refers to Mead's self as object or 'Me'). In certain times and situations, however, balancing the 'I' and 'Me' aspects of the self may become quite conflictual, thus calling for appropriate means of intra- and interpersonal conflict resolution (Stryker and Vryan, 2003).

Conflict Theories

Generally speaking, conflict within and between social groups is inevitable because the needs and interests of individuals and ingroups are more or less incompatible with the needs and interests of other individuals or groups. At the core of conflict theories is the phenomenon of power, or more precisely the imbalance of power, in particular when the powerful determine the lives and resources of the underprivileged, and at the same time ignore to a great extent their needs and interests (Bohman, 2005). Conflict theories, as, for example, Marx' and Engels' dialectical theory of history, try to understand the conditions leading to social inequality and injustice. However, Marxism not only provides an explanatory framework for the understanding of social inequality and conflict, but also has an emancipatory element inasmuch as it urges political action to dissolve inequality by endowing the underprivileged with more power and control to allow for a more self-determined conduct of life. Marx and Engels used their theory to explain the differences and conflict between social classes. In principle, however, Marxist theorizing can be applied to all social constellations where inequality and lack of justice cause conflict as, for instance, in feminist theories that deal with social gender inequalities.

Unresolved conflict and the plea for emancipation call for appropriate means of conflict resolution which cover a wide range from physical aggression to negotiation between conflict parties. In order to ensure that basic human rights are not violated, socialization for negotiation and constructive conflict resolution is a vital prerequisite. At a philosophical level, Habermas (1984, 1987), a prominent contemporary proponent of critical theory, has suggested developing the art of 'communicative competence' to handle conflicts in a so-called 'ideal discourse situation.' This means that all participants in discourse are granted equal opportunity to express their own point of view and to comment critically on the contributions of their fellow participants, keeping in mind that the ultimate goal is to find a solution that all participants can live with. At a more practical level, specific procedures have been worked out to enhance constructive communication and conflict resolution skills, particularly for the family, school, and work context (Bercovitch and Jackson, 2009).

Elements of an Integrative Framework for Studying Socialization and Education

Based on the core anthropological assumptions and theoretical approaches described in the preceding sections, an integrative framework for the study of socialization and educational processes must at least cover the following five aspects.

Units of Environmental Influence

Since the developing person is a part of different and progressively expanding environments, the units of analysis should comprise all settings that may exert direct or indirect influences on the individual. Bronfenbrenner's (2005) ecological systems approach to human development provides an excellent framework for this purpose. By distinguishing between four systemically interrelated levels of developmental contexts, that is, the micro-, meso-, exo-, and macrosystems, the scope of the framework is sufficiently broad to encompass all possible socializing influences that an individual might have to deal with. More specifically, Super and Harkness (1994) have introduced the concept of 'a developmental niche' to describe the conditions that constitute the developmental context of a particular person, especially a particular child. According to these authors, there are three major components of the developmental niche, that is, (1) the physical and social contexts of everyday life, (2) culturally regulated customs of child care and child rearing, and (3) particular psychological characteristics of a child's parents. Together these three components constitute the proximal context that determines the child's experiential field. On the whole, broader ecological systems as well as more specific aspects of the developmental niche form the opportunity structures of the developing person.

Characteristics of the Individuals to be Socialized

Within systems of interacting persons the characteristics of the individuals to be socialized play an important role in shaping the processes and outcome of socialization as a result of their life history (Rhodewalt, 2008). Particularly salient individual characteristics that moderate and mediate socializing influences are (1) basic personal characteristics (e.g., genotype, health, and maturational status of cognitive, motivational, and temperamental dispositions); (2) characteristic adaptational strategies (e.g., information processing, coping and defense mechanisms, and volitional and emotion regulation processes); and (3) typical forms of experiencing the self and the world (e.g., self-concepts, experience of personal identity and coherence, and internal representations of relationships, situations, and environments).

Proximal Processes

To combine the characteristics of a person and his or her environment in a meaningful way, proximal processes, that is, reciprocal interactions between the human organism and the persons, objects, and symbols in its environment (Bronfenbrenner, 2005), are presumed to produce specific socialization outcomes. More specifically, with respect to personality development Caspi and Shiner (2006) have called attention to several kinds of processes explaining developmental diversity and continuity (e.g., environmental elicitation, construal, selection, and manipulation of person–environment transactions).

Goals and Values

In the behavioral and social sciences there is disagreement as to whether or not goals and values governing socialization and education should be incorporated as normative statements in corresponding theories, as is clearly the case in conflict theories of socialization. Although goals and values are undoubtedly objects of socialization theories and research, this controversy remains unresolved. However, even if the originators of socialization theories deliberately restrict themselves to descriptive and explanatory statements, such theories can nevertheless contribute to a great extent to the clarification of socialization goals, and to a better understanding of their antecedents and consequences. Thus, theories of socialization, and, particularly, corresponding research findings, provide valuable information that can be used to make informed choices with respect to one's own beliefs.

Self-socialization

Based on the anthropological assumptions presented above, socialization consists not only, as Mead (1934) contended, of the 'importation' of social symbols into an individual's mind, but deals also with the capacity to select and create personally and socially meaningful goals, due to the individual's progressively increasing action competence and freedom of choice. The latter process refers to the principle of self-socialization or self-cultivation within the limits of personal and sociocultural opportunity structures comprising informal and formal institutions (e.g., families, schools, vocational education, and training institutions). In this context, human beings are creating themselves and the culture in which they live. Moreover, self-socialization enables them to work on the lifelong project of designing their lives in a personally and communally rewarding way (Schneewind, 2004). Thus, theories of socialization and education are not only an outgrowth of humans' cultural activity but serve also as a critical guide for making well-informed choices to optimize the process of self-socialization.

This article is a revision of the previous edition article by R.D. Parke and R. Buriel, volume 21, pp. 14516–14522, © 2001, Elsevier Ltd.

Abstract

This article discusses the role of family in the process of socialization in infancy and childhood. This takes several forms, including treating the family as a social system in which parent–child, marital, and sibling subsystems are recognized. The family socialization process is also recognized within an ecological perspective to appreciate how family environments shape and constrain their socialization practices. Specifically, the impact of social change, socioeconomic status, and ethnicity is discussed.

Socialization is the process by which children acquire the values, standards of behavior, attitudes, and skills that are viewed as appropriate to the culture in which the child resides. Many agents play a role in the socialization process including family, peers, schools, and the media. It is assumed that these various agents function together rather than independently. Families have been recognized as an early pervasive and highly influential context for socialization. Children are dependent on families for nurturance and support from an early age, which accounts, in part, for their prominence as a socialization agent.

Contemporary Perspectives on Family Socialization Theory

Several themes are evident in current theoretical approaches to socialization. First, the rise of systems theory (Minuchin, 1974; Parsons, 1951; Sameroff, 2009) has transformed the study of socialization from a parent–child focus to an emphasis on the family as a social system. To understand fully the nature of family relationships, it is necessary to recognize the interdependence among the roles and functions of all family members. It is being increasingly recognized that families are best viewed as social systems. Consequently, to understand the behavior of one member of a family, the complementary behaviors of other members also need to be recognized and assessed. For example, as men's roles in families shift, changes in women's roles in families must also be monitored.

A closely related theme involves the recognition of the importance of the historical time period in which the family interaction is taking place (Elder and Shanahan, 2006; *see* Life Course: Sociological Aspects). Historical time periods provide the social conditions for individual and family transitions: examples include the 1930s (the Great Depression), the 1980s (Farm Belt Depression), or late 2000s (The Great Recession). Across these historical time periods, family interaction may, in fact, be quite different due to the unique conditions of the particular era. In order to understand the nature of parent–child relationships within families, a multilevel and dynamic approach is required. Multiple levels of analysis are necessary in order to capture the individual, dyadic, and family unit aspects of operation within the family itself as well as to reflect the embeddedness of families within a variety of extrafamilial social systems (*see* Life Course and Event History Analysis). The dynamic quality reflects the multiple developmental trajectories that warrant consideration in understanding the nature of families in infancy. Distinctions among different developmental trajectories, as well as social change and historical period effects, are important because these different forms of changes do not always harmonize (Modell and Elder, 2002). For example, a family event such as the birth of a child may have more effect on a man who has just begun a career than on one who has advanced to a stable occupational position. Moreover, individual and family developmental trajectories are embedded within both the social conditions and the values of the historical time in which they exist. The role of parents as socialization agents is responsive to such fluctuations.

Consistent with a family systems viewpoint, recent research has focused on a variety of subsystems, including parent–child, marital, and sib–sib systems. We employ a tripartite model to understand the parent–child subsystem and the relation between this parent–child subsystem and children's social adaptation. The most common pathway is the parent–child relationship. Parents may influence their children through a second pathway namely in their role as direct instructor, educator, or consultant. In this role parents may explicitly set out to educate their children concerning appropriate norms, rules, and morals of the culture. In a third role, parents function as managers of their children's social lives and serve as regulators of opportunities for social contacts and cognitive experiences (Parke et al., 1994). In this article, we will focus on each of these pathways, as well as marital and sibling subsystems as contexts for socialization. Finally, we will examine the determinants of parental socialization strategies.

Quantitative and Qualitative Assessments of Mother and Father Involvement in Intact Families

In spite of current shifts in cultural attitudes concerning the appropriateness and desirability of shared roles and equal levels of participation in routine caregiving and interaction for mothers and fathers, the shifts toward parity are small but nonetheless real in the majority of intact families. Fathers spend less time with their infants, children, and adolescents than mothers not only in the United States but in other

countries such as Great Britain, Australia, France, and Belgium (Zuzanek, 2000). Mothers and fathers differ in the amount of time that they spend in actual interaction with their children. Pleck (2010) documents that fathers' involvement has increased slowly. Compared to the 1970s, proportional engagement (relative to mothers) was about 33%, whereas accessibility was approximately 50%. In contrast, recent estimates for the 1990s suggest that proportional engagement increased to approximately 70%, whereas accessibility was over 70%. Studies of African-American and Hispanic-American families confirm the pattern found for European Americans. Middle-class and lower-class African-American and Latino fathers were less involved in caregiving with their infants than mothers (Roopnarine, 2004; Roopnarine et al., 2005). Comparisons across ethnic groups (African, Hispanic, and European American) revealed few differences in the level of father involvement (Yeung et al., 2001).

Fathers participate less than mothers in caregiving but spend a greater percentage of the time available for interaction in play activities than mothers do. In North American families, fathers regardless of ethnicity (European American, African-American, or Hispanic-American) spent a greater percentage of their time with their infants in play than mothers, although in absolute terms mothers spent more time than fathers in play with their children (Yeung et al., 2001). The quality of play across mothers and fathers differs too. With infants and toddlers, fathers play more physically arousing games than mothers. In contrast, mothers play more conventional motor games or toy-mediated activities, and are more verbal and didactic (Parke, 1996, 2002). As children develop, fathers become more involved in physical/outdoor play interactions and fixing things around the house and garden, whereas mothers are more actively involved in caregiving and household tasks, in school work, reading, playing with toys, and helping with arts and crafts. In adolescence, the quality of maternal and paternal involvement continues to differ. Just as in earlier developmental periods mothers and fathers may complement each other and provide models that reflect the tasks of adolescence – connectedness and separateness. Recent evidence suggests that fathers may help adolescents develop their own sense of identity and autonomy by being more 'peer-like' and more playful (joking and teasing) which is likely to promote more equal and egalitarian exchanges (Larson and Richards, 1994). However, physical play is not such a central part of the father–child relationship in all cultures: mother–father differences in the amount of play are not evident in Sweden or Israeli Kibbutzim and several cultures (India, China, Africa), physical play is less common for either fathers or mothers (Shwalb et al., 2013).

Why do mothers and fathers play differently? Both biological and environmental factors probably play a role. Experience with infants, the amount of time spent with infants, the usual kinds of responsibilities that a parent assumes – all of these factors influence the parents' style of play. The fact that fathers spend less time with infants and children than mothers may contribute as well. Fathers may use their distinctive arousing style as a way to increase their salience in spite of more limited time. Biological factors cannot be ignored in light of the fact that male monkeys show the same rough and tumble physical style of play as American human fathers. Perhaps predisposing biological differences between males and females may play a role in the play patterns of mothers and fathers. At the same time, the cross-cultural data underscore the ways in which cultural and environmental contexts shape play patterns of mothers and fathers and remind us of the high degree of plasticity of human social behaviors.

Assessing Parent–Child Interaction: Two Approaches

Two approaches to this issue of the impact of parent–child interaction on children's socialization outcomes have been utilized: (1) a typological approach which focused on styles of child-rearing practices and (2) a social interaction approach which focused on the nature of the interchanges between parent and child.

The Typological Approach

The most influential typology has been offered by Baumrind (1973), who distinguished between three types of parental child-rearing typologies: authoritative, authoritarian, and permissive. Authoritative parents were not intrusive and did permit their children considerable freedom within reasonable limits, but were firm and willing to impose restrictions in areas in which they had greater knowledge or insight. In general, high warmth and moderate restrictiveness are associated with the development of self-esteem, adaptability, and social competence. In contrast, the authoritarian parents were rigid, power-assertive, harsh, and unresponsive to the children's needs. These children were often found to be unhappy, conflicted, and neurotic. For permissive parents, in spite of their reasonably affectionate relationship with their children, their excessively lax and inconsistent discipline and encouragement of the free expression of their children's impulses were associated with the development of uncontrolled, impulsive behavior in their children. Baumrind has followed these types of parents and their children from the preschool period through adolescence. She found that authoritative parenting continued to be associated with positive outcomes for adolescents as with younger children and that responsive, firm parent–child relationships were especially important in the development of competence in sons. Moreover, authoritarian child rearing had more negative long-term outcomes for boys than for girls (Baumrind, 1991).

Maccoby and Martin (1983) extended the Baumrind typology and included a fourth type of parenting style, called disengaged, which is characterized by neglect and lack of involvement. These parents do whatever is necessary to minimize the amount of time and effort of the interaction with their child (Maccoby and Martin, 1983). In infants, such a lack of parental involvement is associated with disruptions in attachment; in older children it is associated with impulsivity, aggression, noncompliance, and low self-esteem (Sturge-Apple et al., 2010).

The typological approach has been challenged on several fronts. First, questions remain concerning the processes that contribute to the relative effectiveness of these different styles. Second, it is unclear whether parenting styles are, in part, in response to the child's behavior. Placing the typology work in

a transactional framework would argue that children with certain temperaments and/or behavioral characteristics would determine the nature of the parental style. A third concern is the universality of the typological scheme. Studies have raised serious questions about the generalizability of these styles across either socioeconomic status (SES) or ethnic/cultural groups. In lower SES families, parents are more likely to use an authoritarian as opposed to an authoritative style, but this style is often an adaptation to the ecological conditions such as increased danger and threat that may characterize the lives of poor families (Furstenberg et al., 1999). Furthermore, studies find that the use of authoritarian strategies under these circumstances may be linked with more positive outcomes for children (Dodge et al., 2005). A second challenge to the presumed universal advantage of authoritative child-rearing styles comes from cross-ethnic studies. In Chinese families, authoritarian styles of child rearing are more common and some have argued that the application of these stylistic categories to Chinese parents may be 'ethnocentric and misleading' (Chao, 1994: p. 1111). Finally, in cultures where physical punishment is more normative (e.g., Thailand, the Philippines) the negative effects on children are lessened (Gershoff et al., 2010). Both contextual and cultural considerations need more attention in typological approaches to child rearing.

The Parent–Child Interactional Approach to Socialization

Research in this tradition is based on the assumption that face-to-face interaction with parents may provide the opportunity to learn, rehearse, and refine social skills that are common to successful social interaction with other social partners. The style of the interaction between parent and child is linked to a variety of social outcomes including aggression, achievement, and moral development. Parents who are responsive, warm, and engaging are more likely to have children who are more socially competent (Grimes et al., 2004). In contrast, parents who are hostile and controlling have children who experience more difficulty with age-mates. Moreover, these findings are evident in the preschool period, middle childhood, and adolescence (Harrist et al., 1994; Parke and Buriel, 2006). Although there is an overlap between mothers and fathers, evidence is emerging that fathers make a unique and an independent contribution to their children's social development. Studies (Hart et al., 1998; Isley et al., 1996) have shown that fathers continue to contribute to children's social behavior with peers even after accounting for the mothers' contribution. Although father involvement is quantitatively less than mother involvement, fathers have an important impact on their offspring's development. Quality rather than quantity of parent–child interaction is the important predictor of cognitive and social development.

Parental Instruction, Advice Giving, and Consultation

Learning about relationships through interaction with parents can be viewed as an indirect pathway since the goal is often not explicitly to influence children's social relationships with extrafamilial partners such as peers. In contrast, parents may influence children's relationships directly in their role as a direct instructor, educator, or advisor. In this role, parents may explicitly set out to educate their children concerning appropriate ways of initiating and maintaining social relationships and learning social and moral rules. Research suggests that young children in preschool and early elementary school gain competence with peers when parents supervise and facilitate their experiences, whereas among older children (middle school and beyond), greater parental supervision and guidance of children's peer relationships may function more as a remedial effort (Parke and O'Neil, 2000).

As children grow, the forms of management shift from direct involvement or supervision of the ongoing activities of children and their peers to a less public form of management, involving advice or consultation concerning appropriate ways of handling social problems. In a recent longitudinal study, McDowell and Parke (2009) found that parental advice giving predicted children's social competence, and, in turn, social acceptance 1 year later.

Parents as Managers of Children's Opportunities

Both fathers and mothers play an important role in the facilitation of their children's peer relationships by initiating informal contact between their own children and potential play partners, especially among young children (Reich and Vandell, 2011). However, from infancy through middle childhood, mothers are more likely to assume the managerial role than fathers (Parke, 2002). In infancy, this means setting boundaries for play, taking the child to the doctor, or arranging day care. In middle childhood, it was found that mothers continue to assume more managerial responsibility (e.g., directing the child to have a bath, to eat a meal, or to put away toys).

Parents make choices about neighborhoods and schools as well as the formal and informal activities in which their children can participate. In these ways, "parents act as designers when they seek to control or influence the settings in which children are likely to meet and interact with peers" (Ladd and Pettit, 2002: p. 286). These design decisions can influence children's social and academic outcomes. McDowell and Parke (2009) found that both mothers' and fathers' provision of opportunities for their fourth grade child was related to higher levels of positive social competence in fifth grade. Instead of viewing parents as acting alone in their designer roles, we prefer to view parents and children as codesigners in recognition of children's roles as shapers and negotiators across development. Many decisions are influenced by children's and parents' needs, wishes, and decisions.

Beyond the Parent–Child Dyad: The Marital and Sibling Subsystem as a Contributor to Children's Socialization

Children's experiences in families extend beyond their interactions with parents. Evidence suggests that children's

understanding of relationships is also shaped through their active participation in other family subsystems (e.g., child–sibling) as well as through exposure to the interactions of other dyadic subsystems (e.g., parent–parent).

Influence of Marital Discord on Child Outcomes

Considerable evidence indicates that marital functioning is related to children's short-term coping and long-term adjustment. Children exposed to marital discord are likely to have poorer quality of interpersonal relationships, including internalizing and externalizing behavior problems, and changes in cognitions, emotions, and physiology (see Cummings and Davies, 2010). Three perspectives have been offered to explain the possible links between marital relationships and children's social relationships. One theoretical framework, the indirect effects model, conceptualized marital discord as an indirect influence on children's adjustment that operated through its effect on family functioning and the quality of parenting. A second model, the direct effects model, focuses on the direct effects of witnessed marital conflict on children's outcomes rather than on the indirect effects. Cummings et al. (2010) have proposed a third model: the interrelations among marital quality, parents' psychological functioning, and children's outcomes. Labeled the 'parental mental health hypothesis,' this alternative focuses on the role of parental psychological functioning in accounting for the effects of marital conflict either as a risk or protective factor. All of these models have received empirical support (*see* Marital Interaction: Effects on Child Development).

The Sibling System as a Contributor to Children's Socialization

Siblings play a critical role in the socialization of children. Most children are likely to spend more time in direct interaction with siblings than parents and this array of interactions between siblings have been found to be typified by greater emotional intensity than the behavioral exchanges that characterize other relationships. Sibling relationships contribute to children's socialization in a number of significant ways (Howe et al., 2010). Through their interactions with siblings, children develop specific interaction patterns and social understanding skills that generalize to relationships with other children. Relationships with siblings may also provide a context in which children can practice the skills and interaction styles that have been learned from parents or others. Older siblings function as tutors, managers, or supervisors for their younger siblings and may function as gatekeepers who extend or limit opportunities to interact with other children outside the family (Zukow-Goldring, 2002). Also paralleling the indirect influence that the observation of parent–parent interaction has on children, a second avenue of influence on children's development is their observation of parents interacting with siblings. These interactions may serve as an important context in which children deal with issues of differential treatment and learn about complex social emotions such as rivalry and jealousy (Dunn, 1993).

Determinants of Family Socialization Strategies

One of the major advances in the field has been recognition of the importance of understanding the determinants of parenting behavior. Belsky (1984) proposed a three-domain model of the determinants of parenting, which included characteristics of the child, personal resources of the parents, and contextual sources of stress and support.

Child Characteristics

Child characteristics take two forms: universal predispositions that are shared by all children and individual differences in particular characteristics. Infants are biologically prepared for social, cognitive, and perceptual challenges and these prepared responses play a significant role in facilitating children's adaptation to their environment. Under the influence of recent advances in behavior genetics, there is increasing recognition of the role of individual differences in child temperament on parenting behavior (Rothbart, 2011). Although debates about the relative contributions of genetic and experiential factors to the emergence of individual differences in temperament continue (Reid et al., 2002), temperament clearly is a determinant of parental socialization tactics. Infants with difficult temperaments elicit more arousal and distress from caregivers than less difficult infants (Sanson et al., 2011). Children who are more difficult may elicit increasingly coercive strategies from parents (Reid et al., 2002). Alternatively, fearful children may respond optimally to subtle parental socialization strategies (Kochanska et al., 2007). Other characteristics, in addition to temperament, have been examined, including activity level, social responsiveness, and compliance level. In general, the more active, less responsive, and more noncompliant children elicit more negative parenting and more negative parental arousal and affect (Crouter and Booth, 2003). The impact of these individual differences on parental socialization behavior is not independent of environmental conditions. Crockenberg and Leerkes (2003) showed that the impact of a difficult infant temperament on the parent–infant attachment relationship varied as function of the degree of social support available to the mother, which underscores the potential modifiability of temperament-based influences.

Personal Resources

A variety of studies support the prediction that personal resources – conceptualized as knowledge, ability, and motivation to be a responsible caregiver – alter parenting behaviors (Belsky, 1984). Particularly striking are recent studies of how parental psychopathology such as depression will alter parenting behavior (Goodman and Gotlib, 2002). When interacting with their infants, depressed mothers show flat affect and provide less contingent stimulation than nondepressed mothers; in turn, their infants showed less attentiveness, more fussiness, and lower activity levels. Differences are particularly evident when depression is protracted and not merely transient (Campbell et al., 1995). These differences in interaction may place the infant at risk for later developmental problems. Infants of depressed mothers are more likely to develop insecure attachments

(Goodman and Gotlib, 2002). Other investigations have found links between severe and chronic depression and disorganized attachment behavior (Lyons-Ruth and Jacobvitz, 2008).

Social Support and Family Socialization Strategies

Recognition of the role of the community and community agents as modifiers of family interaction is necessary for an adequate theory of socialization. Social capital in a community can aid parents' socialization of their children through several pathways. First, when parents and children have community ties, more social support is available. Second, parental awareness of community services and their participation in shaping the institutions of the community promote the maintenance of values and norms that influence their children. Third, parental participation with their children enables closer supervision of children and reduces the time children spend with their own peers. The concept of social capital embodies the notion not only that parenting is a community enterprise (Elder and Conger, 2000) but also that children and adults are active players in the distribution of social capital. More attention needs to be given to children's role as active agents in this process.

SES as a Determinant of Family Socialization Strategies

There is a long history of research concerning the links between SES and/or social class and parenting beliefs and practices. In contrast to traditional assumptions that SES is a static state, SES is a dynamic concept. Moreover, most scholars agree that SES is multiply determined, and therefore the links with parenting are likely to be multiple as well. Over the course of childhood and adolescence, families change social class and change is greatest in the youngest ages. Over 50% of American children change social class prior to entering school (Featherman et al., 1988). In spite of the controversies surrounding this variable, there are SES differences in parental socialization practices and beliefs. Lower SES parents are more authoritarian and more punitive than higher SES families (Conger and Dogan, 2007; Hoff et al., 2002). Second, there are more SES differences on language measures than on nonverbal measures with higher SES mothers being more verbal than low SES mothers (Hoff et al., 2002). Some SES differences are independent of race and poverty. In China, where there are relatively small differences in income across groups who vary in terms of education, less educated parents used more imperatives with their toddlers than better educated mothers (Tardif, 1993). Similarly, studies of cognitive socialization found clear SES differences in African-American lower-class and middle-class families (Hess and Shipman, 1965).

Ethnicity as a Determinant of Family Socialization Strategies

Cross-cultural and intracultural theories have emphasized the importance of socialization goals, values, and beliefs as organizing principles for understanding cultural variations (Harkness and Super, 2002). In contrast to the older cultural deficit models of socialization, recent models emphasize how ecological demands shape socialization goals, values, and practices, and are viewed as adaptive strategies to meet the demands of the ecological settings. In the past, cultural deficit models were popular explanations for the socialization and child outcome differences observed between ethnic minorities and Euro-Americans. The focus on ethnic minority families has shifted away from majority–minority differences in developmental outcomes and more toward an understanding of the adaptive strategies ethnic minorities develop in response to both majority and minority cultural influences on their development.

The parents' individual history of interaction with the larger sociocultural context, including their awareness of their ethnic group's history within the larger society, affects the manner in which they socialize their children. An important dimension of socialization in ethnic minority families is teaching children how to interact effectively in dual cultural contexts; the context of their ethnic group and the context of the larger Euro-American society. Harrison et al. (1990) have adopted an ecological orientation to explain the diverse environmental influences that contribute to the socialization of ethnic minority children. They conceptualize the socialization of ethnic minority children in terms of the interconnectedness between the status of ethnic minority families, adaptive strategies, socialization goals, and child outcomes. Emerging out of the adaptive strategies of adults are the socialization goals that they endeavor to inculcate in children to help them meet the ecological challenges they will face as ethnic/racial minorities in a class- and race-conscious society. Ethnic/racial pride and interdependence are two important socialization goals that enable ethnic minority children to function competently as members of both their minority culture and the larger society (Harrison et al., 1990).

Research needs to take into account the acculturation level of parents and children in recent immigrant families and the effects it has on family processes and child outcomes. Intergenerational differences in acculturation can create role strains between parents and children that have implications for child-rearing styles, disciplinary practices, and overall parent–child relations. Together with acculturation, recognition of biculturalism as both an adaptation strategy and socialization goal is important. The effects of prejudice and discrimination on ethnic minorities, in such areas as social and emotional development, ethnic identity, and achievement motivation, deserve more attention. Language development research should also give greater attention to second-language acquisition (usually English) and bilingualism and its relation to cognitive development and school achievement. More attention must also be given to the role of ethnic minority fathers, grandparents, and extended family members in the socialization of children (*see* Parenting in Ethnic Minority Families: United States). Finally, observational studies with ethnic/racial minority families have the potential for yielding a contextual richness about the family environments of ethnic/racial minorities that can lead to more culturally relevant insights and theories about their socialization experiences.

The Impact of Social Change on Family Socialization

Families are not static but dynamic and are continuously confronted by challenges, changes, and opportunities.

A number of society-wide changes have produced a variety of shifts in the nature of family relationships. Fertility rates and family size have decreased, the percentage of women in the workforce has increased, the timing of onset of parenthood has shifted, divorce rates have risen, and the number of single parent families has increased (Parke, 2013). These social trends provide an opportunity to explore how families adapt and change in response to these shifting circumstances and represent 'natural experiments' in family coping and adaptation. Moreover, they challenge our traditional assumptions that families can be studied at a single point in historical time since the historical contexts are constantly shifting. Our task is to establish how socialization processes operate similarly or differently under varying historical circumstances. Some of these changes are scheduled or planned, such as reentry into the workforce or delaying the onset of parenthood; other changes, such as job loss or divorce, are unscheduled or nonnormative transitions. According to a life-course view, both scheduled and unscheduled transitions need to be examined to fully appreciate how these different types of changes alter family socialization strategies (Elder and Shanahan, 2006). These family transitions are adult-focused in contrast to child-focused transitions (e.g., entry to day care or junior high school) and underscore our assumption that adult developmental issues need to be directly addressed to understand how these transitions alter parental socialization beliefs and behaviors. At the same time, child developmental status plays a major role in determining how adults respond to these transitions. It is insufficient to focus on individual levels of analysis – either adult or child since individual, dyadic, triadic, and family units each follows their own developmental trajectory and the interplay among these separate developmental trajectories can produce a diverse set of effects on children. The role of these units (i.e., individual, dyad, or family) in modifying the impact of family transitions will vary as a result of these interlocking developmental curves. Both the timing and nature of family transitions and reactions to these alterations will be determined by the points at which particular individuals, dyads, triads, or families fall along their respective developmental life-course trajectories. Moreover, individual families can vary widely in the particular configuration of life-course trajectories. The particular configurations of these multiple sets of developmental trajectories need to be considered to understand the impact of societal change on families.

Conclusion

Socialization is a multiply determined process; while our focus has been on families as central socialization agents, it is critical to recognize the roles of other social agents such as schools, peers, and the mass media in this process. A fuller understanding of socialization will come from more attention to the interplay among these diverse agents and how cultural and ethnic background influence socialization practices and outcomes.

Abstract

Societal impact assessment (SIA) refers to a set of guidelines and principles to identify the societal effects of new technologies, programs, and projects. Starting in the domain of environmental issues, SIA has expanded into other areas where new technologies start to shape the everyday life of citizens. With a strong focus on participatory and anticipatory strategies, SIA attempts to establish a broader understanding of technology taking into account the perspective of different stakeholders. This article briefly reviews key elements of SIA and then discusses its potential, using privacy impact assessment as a test case.

Introduction and Context

While traditionally social impact assessment (SIA) is about analyzing, monitoring, and managing the social consequences of development (Vanclay, 2003, 2006), this article proposes to broaden the perspective and conceptualize 'Societal Impact Assessment.' The term 'societal' encompasses the analysis of anything affecting human, natural, or artifactual systems. This allows for significant conceptual innovation: while hitherto SIA has worked under the assumption that actors, interests, and consequences of programs, projects, actions, and research can be identified, 'Societal Impact Assessment' acknowledges the potential of technology to alter society as such, rendering this altering almost irreversible (e.g., introduction of new energy sources, etc.). It thus allows to capture structural changes affecting society as a whole, leading to a new level of normality without stopping at the limits of a well-circumscribed development site or the identification of actors and vested interests. We therefore use the term 'Societal Impact Assessment' throughout this article.

The idea of conducting SIAs is a child of reflexive modernity (Beck, 1992). While science and technology for a long time were perceived as social forces of unambiguous progress liberating mankind from burdens and hazards of life and nature, the advent of modern technologies affecting society in unforeseen ways gradually reshaped the public image of science. Critical reappraisals of science and technology followed on spectacular scientific breakthroughs, paving the way for new technologies, like, e.g., nuclear weapons. Concerned scientists congregated at meetings like the *Pugwash* Conferences to critically reflect on the societal impact of their work. While the main focus of these debates was on the consequences of scientific knowledge, applied to create weapons of mass destruction, at the same time a critical stance toward science and technology emerged in the debate about environmental hazards. Rachel Carson's book *Silent Spring*, first published in 1962, is today perceived as the manifesto launching modern environmentalism (Carson, 1962). Carson critically examined the detrimental effects of pesticides, hitherto seen as benevolent chemical agents in agriculture. Concerned scientists from different disciplines started to take a critical look on their own achievements.

While the natural sciences came into the focus of societal critique in this period in the first decades after WW II, the social sciences had their heyday in the 1960s providing a scientific toolbox for planned social change and improvement. The Great Society Programme in the United States, initiated by American president Lyndon B. Johnson, heavily relied on the expertise of social scientists. Their task was to contribute to the analysis and definition of social problems to be addressed by socio-technical policies and to design the adequate measures to combat social inequality, crime, and poverty. But soon critique from within the academic community emerged, showing with the very same methods and approaches used to analyze and define social ills, that the cure might be worse than the disease. Social programs, designed to reduce poverty, so the critics claimed (see e.g., Moynihan, 1993), would rather stabilize a 'culture of poverty' than create greater social equality.

What can be demonstrated here is how scientific knowledge in different disciplines was transformed into a productive force, creating new technologies and changing society on a massive scale, thus putting the issue of social responsibility of science on the agenda. SIA was one strategy to develop an institutionalized and rational response from within the scientific community to this situation. In 1981 the International Association for Impact Assessment (IAIA) was established to provide a professional platform for the implementation of SIA. Membership of the IAIA was recruited from the academic community, private consultancies (who saw an emerging business case in SIA), government, and from industries. Other forms of institutionalization followed, such as the parliamentary technology assessment bodies (PTA) in different countries, advising Parliaments on the effects of new technologies. PTA established an international association at the European level with the foundation of the European Parliamentary Technology Assessment Network (EPTA).

The main focus of impact assessment activities was on environmental effects and sustainability. Green issues had a high political visibility and attracted substantial public attention. With the spread of different technologies into everyday life, new fields came into focus, starting from health and medicine, to nanotechnologies to energy and transport, and in recent times to issues of privacy and data protection with the spread of new communication and surveillance technologies. In many national jurisdictions conducting an impact assessment has become a mandatory element of implementing new technologies or projects.

Conceptually, SIA is a multidisciplinary professional enterprise. It requires technical expertise in different scientific fields and at the same time a sound understanding of broader societal issues and nontechnological effects of a given technology. In its broadest sense, SIA focuses on issues of human rights, social inequality, environmental issues, and public participation. These main topics can be spelt out in different directions depending on the problem at hand. At the same time SIA by definition is tied into a political field (Freudenburg, 1986), and thus establishing a position not contaminated by vested interests in the analysis and following a clear process of objective assessment is of utmost importance. In essence, there are two ways of framing the SIA: "In addition to being a field of research, SIA is conceived as being a methodological approach or framework" (Esteves et al., 2012: p. 34).

Different forms of SIA can be distinguished with regard to the scope of the approach taken. In a more narrow understanding SIA will investigate whether a given project develops within an existing regulatory framework, e.g., environmental standards, defined by law are met. In a broader sense it will include participatory elements involving different stakeholders and experts in a discursive exchange about a technology, project or program at hand (Harvey, 2011). Finally SIA can be designed in a more reflexive way, feeding back into the core processes of technology development by addressing the rationale and rationality of research and development from a societal impact perspective. This strategy is pursued predominantly in constructive technology assessment (CTA).

Methodologies and Approaches

Different methodologies and guidelines were developed to conduct SIA. Vanclay and Esteves (2011) define a number of consecutive steps to be followed when conducting SIA. Kemp (2011) lists different groups of actors or parties involved to be considered when assessing societal impact. Becker (2001) proposes a two-phase model, with the first, preparatory phase focusing on an analysis of the project under investigation, while the second or main phase makes use of scenario-building techniques to identify the range of future effects of a project. This forward-looking dimension is a key feature of SIA; but at the same time it poses one of the key problems, since the future-oriented logic of risk (see Luhmann, 1993) underlying the scenario technique can have a number of far-reaching consequences with regard to accountability and decision-making processes in the present.

The two main types of problems to be solved with an SIA can be classified as *cognitive* and *social* problems. With regard to cognitive problems, it is difficult to project future trajectories of technological development and impact, the more so when complex systems of systems are involved. Scenario techniques can help to address the problems of complexity, modeling interaction, and cascading effects. But at the same time understanding complex scenarios and discussing the probability of different options often requires detailed expert knowledge not always easily available to all groups of stakeholders involved.

Regarding social problems, ensuring an inclusive approach in SIA, i.e., giving all stakeholders and groups involved in an assessment exercise an adequate share of voice can be a quite challenging task. Community participation is sometimes used as a seemingly 'quick fix' for problems, without addressing the root of the issue (which often lies to unequal power distributions that are deeply engrained in polities, and sometimes in the very institutions of the community whose participation is sought). As a result, community participation sometimes takes the form of a tokenistic exercise; once 'affected communities' – or their leaders – have been heard, the respective box can be ticked off, and afterward the rule of previous power relations resumes (Peterman, 2004).

Similar concerns have been voiced about the emphasis on public participation (i.e., the participation of potentially everyone, not only those affected by a project or policy). The "reasons for seeking public participation [in impact assessment exercises are] highly diverse and not always mutually consistent," as O'Faircheallaigh (2010: p. 19) points out, and some projects specify the benefits of public participation only very poorly. The reason for this is that such benefits are treated as self-evident (for a typology of such benefits see O'Faircheallaigh, 2010). Others have argued that public participation only deserves its name when publics are actively involved in decision-making, and their stances have significant influence in the development of the project or policy in question (Bishop and Davis, 2002). To address the challenge, Prainsack (2014) has developed a grid to establish the degree of agency of members of the public vis-à-vis professional experts in a project. This grid aims to assess the strengths and weaknesses of a project from a participatory perspective.

A final problem emerging with public participation is of the NIMBY type. While some stakeholders may oppose to a certain project, because they are immediately affected, others may be supportive, as long as the immediate negative effects are not felt in their own backyards and they have access to the positive effects. An alternative option to the NIMBY position, popularized under the acronym NIABY (Not in Anyone's Backyard) is the wholesale refusal of a technology or project under discussion.

Beginning at an earlier stage of technology development processes, the approach labeled as constructive technology assessment (CTA) looks at the interaction between internal and external forces, developers, users, stakeholders, in the development and design of technologies. CTA's main value, it could be argued, is not about predicting possible future impacts of the technology as accurately as possible – rather, it lies in the dialogue and the interaction it requires the actors to engage in, while developing a technological solution. This dialogue and interaction contribute to enhancing a mutual understanding of each actor's needs and objectives. This is expected to improve problem-solving capacities even if negative impacts occur. This approach is characteristic for CTA. Moreover, CTA clearly sets itself apart from the 'deficit model' of public engagement, where publics are seen in need to be 'educated' about science in order to appropriately understand, and ultimately accept, new science and technology. CTA's approach to public engagement is strongly participatory and dialogical. In other words, the emphasis of CTA does not lie in predicting impacts and facilitating technological development and deployment, but it lies in understanding them (as well as the dynamics which facilitate or impede their occurrence).

It is precisely this understanding of the dynamics underlying the technology development process that opens up opportunities for intervention. These opportunities need to be identified, and then it needs to be specified in what ways such interventions can be most productive (Rip and Schot, 2002).

Understanding the dynamics of development allows one to identify opportunities of intervention, and specify how such interventions can be productive. A better understanding of impact anticipation and appropriate intervention can contribute to mitigating the complexity of the process.

There are three generic strategies CTA pursues (Schot and Rip, 1996): technology forcing, strategic niche management, and alignment. The authors argue that these strategies should be jointly deployed in the field in order to maximize reflexivity, anticipation, and learning processes.

Technology forcing is a term that originates in industry and signifies the setting of standards for industry that cannot be reached with current means and technologies; the standards thus 'force' industry into innovation. In CTA, 'technology forcing' describes the modulation of technology development from the demand side. This implies an inversion of traditional technology assessment (TA) approaches, as it is the formulation of requirements for impacts that drives the development of technology, rather than taking technology as a given.

The other two generic CTA strategies are *strategic niche management* and *alignment*. The former is about the creation of technological niches that, as protected spaces, allow for a safe experimental environment in which the interplay of technology, user practices, and frameworks such as the regulatory context can be looked at. The overarching aim here is to contribute to a more sustainable innovation journey by more rapid reaction to societal changes. *Alignment*, the third strategy within CTA, also looks at the interaction process of the assessment actors, aims to foster mutual understanding and dialogue and thus 'align' different perspectives.

Privacy and Surveillance Impact Assessment – A Test Case

One of the prominent cases for SIA in recent times has emerged out of the spread of surveillance technologies and social media. Electronically mediated communication, new forms of electronic commerce, and the widespread use of mobile phones not only created a technological boost in soft- and hardware development but at the same time opened hitherto unprecedented opportunities for the gathering and processing of person-related data by private enterprises and public authorities. This process of 'datafication' (Mayer-Schönberger and Cukier, 2013) has created a demand for a procedure termed 'privacy impact assessment' (PIA), a term that did not show up on the Social Science Research Network before 2012. Taking PIA as a showcase for SIA processes, problems and potentials of SIA can be neatly demonstrated.

PIA assesses both technologies and practices with regard to the risks they impose for infringements of privacy. The assessment process considers projects, technologies, products, services, policies, programs, and other initiatives (Wright et al., 2013). A PIA requires consultation with stakeholders in order to scan for measures that are necessary and appropriate to mitigate the identified negative impacts.

In 2009, the proposed European General Data Protection Regulation (GDPR) acknowledged the importance of PIA, holding that by engaging both industry and civil society stakeholders, EU Member States are to make sure that a framework for privacy and data protection impact assessments is put in place. A revised draft version of the regulation (European Commission, 2011) stresses the importance of concepts such as transparency, dialogue, and privacy by design. This proposed regulation also foresees, as part of the assessment procedure, a description of planned operations, an evaluation of risks and impacts on specific people and groups (and their freedoms and rights). This plan also has to envision appropriate protection and control measures.

A coherent methodological framework governing PIA has not yet emerged. Assessment requirements vary from case to case, both in scale and in scope, and also with regard to the actors involved. Wright and Wadhwa (2012) compiled a list of 16 steps applicable to both PIA and surveillance impact assessment:

1. Determine whether a PIA (or surveillance impact assessment) is necessary (threshold analysis).
2. Identify the PIA (or surveillance impact assessment) team and set the team's terms of reference, resources, and time frame.
3. Prepare a PIA (or surveillance impact assessment) plan.
4. Determine the budget for the PIA (or surveillance impact assessment).
5. Describe the proposed project to be assessed.
6. Identify stakeholders.
7. Analyze the information flows and other impacts.
8. Consult with stakeholders.
9. Determine whether the project complies with legislation.
10. Identify risks and possible solutions.
11. Formulate recommendations.
12. Prepare and publish the report, e.g., on the organization's Web site.
13. Implement the recommendations.
14. Ensure a third-party review and/or audit of the PIA (or surveillance impact assessment).
15. Update the PIA (or surveillance impact assessment) if there are changes in the project.
16. Embed privacy awareness throughout the organization and ensure accountability (cf Wright and Raab, 2012: p. 615).

This list is similar to others developed in SIA handbooks. It covers the major steps, actors, and topics to be addressed in an impact assessment.

What makes PIA a good case to demonstrate the workings and problems of an SIA is the involvement of complex interlinked technologies, the challenge to find a regulatory framework for a technology that easily escapes traditional juridical wisdom, the pervasiveness of the problem affecting practically the whole of the population in Western democracies, the role of the state as a relevant stakeholder with conflicting interests (guaranteeing by the same token security and privacy of the citizens), the a-territorial character of the domain to be regulated (i.e., cyberspace), and differential levels of awareness of the problem among the stakeholders.

The primary motivation for a PIA can flow from different sources: either the industry providing privacy affecting services is working under a regulatory regime, making data-protection mandatory or a group of civil society actors voices concern over the dangers of unrestricted data processing capabilities by industry or public authorities. With PIA it has often been the academic community of legal scholars or surveillance studies experts raising the issue of data protection and rallying for a PIA. As with many other technologies the immediate effects, potential hazards, and threats are not easily visible for the lay user despite the fact of being affected on a daily basis. Having a regulatory framework in place making SIA mandatory can be an asset in such a situation, since the force of law can stand in for the force of public concern. The problem though is that PIA recommendations often entail the element of an active user. In order to provide for adequate privacy protection citizens have to adhere to certain rules and practices and thus become activated in implementing PIA recommendations. At this point an intricate problem can be analyzed: when assessing the impact of a technology, program, or project participatory processes of stakeholder involvement often produce ambiguous results with regard to the evaluation of the impact as positive and desirable or negative. While in the context of a PIA, a high standard of privacy and data protection as such may be desirable the costs involved in maintaining such high levels have to be weighed against the gains. The textbook case for this is the use of loyalty cards. While such costumer convenience systems regularly have tremendous effects on the privacy of the users (collecting data about shopping habits and provide the basis for social sorting), they nonetheless are often seen as convenient gadgets from the consumers' perspective. Trading in privacy for convenience is a standard dilemma encountered in the context of PIA. A similar dilemma emerges when public authorities such as law enforcement agencies collect and process person-related data of citizens. Here the trade-off between privacy and security emerges. This points to another fundamental problem of impact assessment projects. Security as an impact defies any rational measurement when defined as the prevention of terrorist attacks. The threat of such attacks provides the pretext for severe privacy-infringing practices by law enforcement agencies. But any positive effects (i.e., nonevents) can hardly be measured, while the negative consequences (increased surveillance and control) are often quite obvious. Also it can be difficult to determine the scope of the phenomena to be assessed. When data and information are traveling at the speed of light around the globe, the problem of privacy and data protection at any given locale or societal context tends to become a global problem in the literal sense, much as global warming or global pollution. Binding legislation is limited to the nation-state and whatever happens beyond these limits is *de facto* beyond the jurisdiction of the state.

Taking PIA as a test case for the programmatic promises of SIA can demonstrate the limits of this approach while at the same time providing arguments for the urgency of adequate impact assessment measures. SIA needs to be developed further to handle problems of the type surfacing in PIA: ambiguous assessments, deterritorialization, limitations of traditional regulatory regimes, and the need of active involvement of stakeholders, not only in the assessment processes but beyond.

Future Perspective: Toward Balanced Risk Awareness

Living in a society soaked with many techno-social systems requires a clear understanding of the effects of technology. Against antitechnological attitudes reemerging in a kind of neo-Luddite move SIA can help to develop balanced risk awareness and open up new institutional spaces for the deliberation of developmental trajectories, using new and different technologies to overcome or curtail the global risks emerging from a naive use of technology. This at the same time requires a new techno-literacy and a democratic political culture of participation in decisions about future developments. SIA can help to foster both and thus will become more relevant.

Societies, Types of

Guillermina Jasso, New York University, New York, NY, USA

© 2015 Elsevier Ltd. All rights reserved.

This article is a revision of the previous edition article by R. Deliège, volume 21, pp. 14530–14536, © 2001, Elsevier Ltd.

Abstract

Societies may be classified along many dimensions – large or small, geographic location, resource base, form of government, kind of economy, and so on. This article describes two new approaches to classifying societies, both grounded in basic sociobehavioral theory, specifically, on Plato's and Aristotle's idea that the ways and means of seeking happiness generate distinctive types of societies. The first approach arises from the new unified theory (NUT) of sociobehavioral forces, which posits three forces from the Mertonian middle range and yields five types of societies (echoing Plato's hint). The second approach is based on four deeper engines of behavior, and yields 15 types of societies (four single-engine societies, six dual-engine societies, four triple-engine societies, and one quad-engine society) plus a null society, with no visible engine of social behavior – for a total of 2^n or 16 societies. In the language of happiness, the first approach is based on three middle-range carriers of happiness and the second on four deeper carriers of happiness. An as yet unanswered question is whether the middle-range carriers of happiness can be derived from the deeper carriers of happiness, or, equivalently, whether the NUT societies can be derived from the deeper-engine societies.

Introduction

Thinking about human behavioral and social phenomena leads in a natural way to classifications of societies. Societies may be classified along many dimensions – large or small, geographic location, resource base, form of government, kind of economy, and so on. Deliège (2001), writing in the first edition of this Encyclopedia, provides a useful overview of such classifications. Grusky and Ku (2008, pp. 13–18) provide a useful classification of stratification systems, conceptually closely related to types of societies, including a handy table. This article describes two new approaches to classifying societies, both grounded in basic sociobehavioral theory, specifically, on Plato's (*Republic*, Book VIII) and Aristotle's (*Politics*, Book 7, Chapter 8) idea that the ways and means of seeking happiness generate distinctive types of societies. The first approach, based on a recent synthesis of theories of three primordial sociobehavioral outcomes (PSOs) from the Mertonian middle range – justice (shorthand for justice and the other comparison processes), status, and power – yields five types of societies, echoing Plato's hint (Jasso, 2008). The second approach is based on four deeper engines of behavior, and yields 15 types of societies (four single-engine societies, six dual-engine societies, four triple-engine societies, and one quad-engine society) plus a null society, with no visible engine of social behavior – for a total of 2^n or 16 societies. Extending to status and power Rayo and Becker's (2007) evocative idea that comparison is a 'carrier of happiness,' the first approach is based on three middle-range carriers of happiness and the second on four deeper carriers of happiness. An as yet unanswered question is whether the middle-range carriers of happiness can be derived from the deeper carriers of happiness, or, equivalently, whether the NUT societies can be derived from the deeper-engine societies. The second approach has not received even a hundredth of the theoretical and empirical scrutiny of the first, and is included here for the sake of comprehensiveness and to honor the abiding challenge to probe ever more deeply.

Types of Societies, in the New Unified Theory of Sociobehavioral Forces

Brief Overview of the New Unified Theory

The new unified theory (NUT) of sociobehavioral forces integrates theories describing three sociobehavioral processes – status, power, and justice (and the other comparison processes) – generating identity and (partially) happiness and bringing under a single theoretical umbrella diverse mechanisms together with their effects across disparate domains and for both individuals and societies (Jasso, 2008). The integration is made possible by the remarkable similarity of the internal core of the theories.

The key foundational idea can be traced to Plato (*Republic*, Book VIII) and Aristotle, in Aristotle's (*Politics*, Book 7, Chapter 8) words: "Different men seek after happiness in different ways and by different means, and so make for themselves different modes of life and forms of government." The new theory formalizes the 'different ways and … different means' of seeking happiness by the operation of three sociobehavioral forces, in which the PSOs which give each force its name (status, power, and justice) are generated by distinctive mechanisms from personal quantitative characteristics (such as beauty and wealth) within groups formed by categories of personal qualitative characteristics (such as nativity, race, and gender). To illustrate, status may be generated from academic skill within a classroom, or self-esteem from tennis-playing skill on the court. Each bundle of elements, say, status–skill–classroom, simultaneously generates an identity and a magnitude of happiness. Different combinations of elements – e.g., power–wealth–club, status–horsemanship–regiment – generate distinctive identities and magnitudes of happiness.

A person's time series of bundles – or, equivalently, time series of identities – together with the associated configuration of elements, describes the person's inner sociobehavioral life in the pursuit of happiness. Some persons dwell on beauty, others on skill, others on possessions, and so on (an aspect of reality captured in Shakespeare's Sonnet 91); concomitantly, some

persons inhabit worlds bounded by race, nativity, or sex; and while some are moved by status, others fix on justice or power.

The configurations of elements in the sociobehavioral profiles of individuals in turn produce the societal configuration. Thus, both individuals and societies come to be seen as materialistic or status-conscious or racialist – or, alternatively, as even-keeled, absent any great preference for status over self-esteem, or wealth over intelligence, or nativity over gender. Like persons, societies are also dynamic, with a time series of configurations based on the profiles of individuals. And models based on the NUT yield a large number of testable predictions (both intuitive and counterintuitive, and including novel predictions) for a wide range of phenomena at both micro- and macrolevels and across disparate topical domains, revealing the thread from the inner sociobehavioral life to the myriad of individual sentiments and behaviors and finally to social phenomena at every scale, from dyads to small groups to nation-states and multinational entities.

A Closer Look at the NUT

The NUT begins with three sets of elements: (1) personal quantitative characteristics, (2) personal qualitative characteristics, and (3) PSOs. The three combine to provide a foundational relation: PSOs are generated by personal quantitative characteristics within groups formed by personal qualitative characteristics.

Personal quantitative characteristics are characteristics of which there can be more or less, or on which a person may rank higher or lower. The first kind – of which there can be more or less – is called *cardinal*; examples are wealth, land, head of cattle. The second kind – on which a person may rank higher or lower – is called *ordinal*; examples include, beauty, intelligence, musical skill.

Personal quantitative characteristics are called *goods* if more is preferred to less and *bads* if less is preferred to more. To illustrate, for most people, money is a good and time in prison is a bad. For simplicity, this article focuses on goods. However, extension to bads is straightforward.

Personal qualitative characteristics are unorderable, categorical personal characteristics. They may be dichotomous – like gender – or polytomous – like race, ethnicity, or religious affiliation. Personal qualitative characteristics give rise to groups and subgroups, with these groups and subgroups defined by the category of a personal qualitative characteristic. For example, the group 'residents of France' is defined in terms of a category of the personal qualitative characteristic 'country of residence,' and the subgroups 'women' and 'men' are defined in terms of categories of the personal qualitative characteristic 'gender.'

The basic idea that there are two kinds of personal characteristics, quantitative and qualitative, and that they differ in their sociobehavioral operation was pioneered by Blau (1974).

The PSOs are outcomes universally desired and deeply social. The sociological literature suggests that there are three – justice (shorthand for the comparison processes), status, and power. As noted, all three are generated by personal quantitative characteristics within groups formed by personal qualitative characteristics. For example, status may be produced by wealth within the population of a city, or by tennis-playing skill within the membership of a country club, or by horsemanship within a military regiment. Associated with each of the three PSOs is a distinctive mechanism and, in particular, a distinctive rate of change. Status and power arise as functions of a personal quantitative characteristic X; justice and the other comparison processes (like self-esteem) arise from the comparison of an actual magnitude of X to a magnitude envisioned, desired, or thought just, denoted X^* – or, as William James ([1891] 1952, p. 200) put it, the comparison of actualities to potentialities, or success to pretensions. Thus, in the basic equations for status and power, there is only one argument, X (or its relative rank), but in the basic equation for justice, there are two arguments, X and X^*.

What kinds of mechanisms connect the Xs and the PSOs? It is well-known that all the PSOs can be generated by the same quantitative characteristic; for example, beauty and wealth generate status, and they generate power, and they generate the comparison outcomes like self-esteem and the sense of justice. If all three PSOs are functions of the same quantitative characteristics, the question arises: What distinguishes them? Or are justice, status, and power merely different names for the same outcome? If we accept, at least provisionally, the possibility that the three PSOs are indeed distinct outcomes, then the challenge is to find the distinguishing feature. A strong contender is the *rate of change*.

In nature there are three rates of change – increasing, decreasing, and constant – and thus a natural and immediate conjecture is that the three PSOs each have a distinctive rate of change and thus the task is to match the three rates of change to the three PSOs. **Figure 1** illustrates the three rates of change in relations in which the PSO increases as X increases. For convenience, X is represented by a relative rank, assuming values from zero to one. But the graphs could as easily be drawn with cardinal magnitudes of X, and all the theoretical development below incorporates both magnitudes and relative ranks of X.

Which sociobehavioral outcome increases at an increasing rate? And which at a decreasing rate? And which at a constant rate?

The sociological literature, in work dating to the early 1950s, suggests that as the quantitative characteristic X increases, status increases at an *increasing* rate (Bales et al., 1951; Goode, 1978; Sørensen, 1979; Stephan, 1952; Stephan and Mishler, 1952) and the comparison outcomes at a *decreasing* rate (Blau, 1964; Jasso, 1978; Wagner and Berger, 1985). Because the literature does not provide a functional form for the relation between the Xs and power (Webster, 2006), the summary proposed by Jasso (2008) suggests that if power is indeed a basic and distinct sociobehavioral outcome – and not merely a synonym for justice or status – then it must vary at a constant rate with the personal quantitative characteristic.

To elaborate briefly, the convexity property of status is evident in the research on frequency of participation in small-group discussions conducted by Bales et al. (1951), Stephan (1952), and Stephan and Mishler (1952), as well as in the range of social situations analyzed by Goode (1978). Meanwhile, the justice and comparison literature notes that the negative second derivative is necessary and sufficient for the properties of deficiency aversion and loss aversion, which are considered essential in a justice evaluation function (Brown, 1986, p. 78; Jasso, 1978; Wagner and

Figure 1 Illustration of three possible rates of change in an increasing function.

Berger, 1985, p. 719) and in comparison processes more generally (Jasso, 1990).

Of course, many functional forms display the increasing or decreasing rate of change proposed for status and comparison, respectively. The sociological literature goes beyond the rate of change and suggests specific functional forms for the status and comparison PSOs. For status, Sørensen (1979) proposed the following function, a function which embeds Goode's (1978) convexity condition:

$$S = \ln\left(\frac{1}{1 - r_X}\right), \qquad [1]$$

where S denotes status, X as before denotes the valued good (i.e., the valued attribute or possession), and r denotes the relative rank on the valued good. Although the valued good can be cardinal or ordinal, the status function notices only its relative rank.

In the case of comparison processes, Jasso (1978, 1990) proposed the following function:

$$Z = \theta \ln\left(\frac{X}{X^*}\right), \qquad [2]$$

where Z denotes any of the comparison outcomes, such as self-esteem or the justice evaluation, X is as above the valued attribute or possession (called in this literature the actual reward), X^* denotes the comparison referent (called the just reward in the special case of justice), and θ is the signature constant whose sign indicates whether the reward is viewed as a good or a bad and whose absolute value denotes expressiveness. When the actual reward equals the comparison referent, the outcome is zero (a neutral point which in the case of justice is called the point of perfect justice); when the actual reward exceeds the comparison referent, the outcome is positive (representing overreward), and when the actual reward is less than the comparison referent, the outcome is negative (representing underreward). Besides satisfying deficiency aversion and loss aversion, this function is also the only function which satisfies two additional conditions, scale invariance and additivity (Jasso, 1990). By additivity, the effect of X on Z is independent of the magnitude of X^*, and the effect of X^* on Z is independent of the magnitude of X. Scale invariance ensures that the outcome Z will be the same regardless of the units in which the reward is measured.

The expressiveness part of the signature constant θ plays an important part in empirical work but can be safely ignored in much theoretical work. The framing part of the signature constant is always important, but can safely be set as positive, given that results for bads are readily established from results on goods. Accordingly, in the rest of this article, the signature constant is fixed at $+1$.

If we provisionally accept the reasoning in the literature and if power is a sociobehavioral force in its own right, different from either justice or status, then we may posit a linear function:

$$P = a + bX \qquad [3]$$

where P denotes power and a and b are the intercept and slope, respectively. In the special case in which the intercept is zero and the slope is one, the function reduces to an identity function.

Power and the comparison processes are also generated by ordinal characteristics, such as beauty and skills of all kinds, or by the relative rank on a cardinal good. When the PSO is status or when the valued goods are ordinal (or the ordinal aspect of cardinal goods), personal qualitative characteristics provide the group or population within which the relative ranks are measured. As well, in the justice case, when the comparison referent is a summary characteristic of a distribution (such as the arithmetic mean, geometric mean, or median), personal qualitative characteristics provide the group or population within which the referent is measured. For example, those groups may be specified as a category of gender, nativity, citizenship, religion, or other qualitative characteristic.

The three PSOs (status, power, and justice) are thought to generate identity, emotion, and a wide range of behavioral and social phenomena. As well, extending to status and power the evocative language used by Rayo and Becker (2007) for comparison, the three PSOs are thought to operate as 'carriers of happiness.' In brief, during intervals when a particular PSO is active, it produces identity and generates happiness. Of course, happiness may also be generated by nonsocial phenomena, such as a beautiful sunset or the fruit of a tree.

Thus, an identity is a three-element bundle, consisting of the PSO, the quantitative characteristic, and the qualitative characteristic – for example, status-wealth-classroom or power-intelligence-dormitory. Persons may be thought of as collections of identities; they come to be characterized by their configuration of elements in the identities, termed *personality*. Similarly, societies are collections of persons; they come to be characterized by their configuration of elements in their members' identities, termed *culture*. Examples of personality in this technical theoretical sense are the status-obsessed, beauty-fixated, and gender-conscious; examples of culture include jock culture, materialistic culture, and racialist culture.

Finally, because status notices only relative ranks while justice and power respond to both amounts and relative ranks, there are five types of societies:

- justice-materialistic
- justice-nonmaterialistic
- status
- power-materialistic
- power-nonmaterialistic

Given that the PSOs generate happiness, this is a modern expression of Plato's idea that there are five types of societies, corresponding to five ways that people seek after happiness (Jasso, 2008).

An immediate natural question is: What do these societies look like? The PSO distribution provides a picture – symmetric or asymmetric, with varying proportions of happy and unhappy people, with extreme values that can range, or not, to depths of unhappiness and heights of happiness, with greater or lesser inequality.

In status, justice-nonmaterialistic, and power-nonmaterialistic societies, the valued good has an ordinal representation, and thus information about the PSO distribution is immediate. The status distribution is a negative exponential, the justice-nonmaterialistic is a positive exponential, and the power-nonmaterialistic is a linear transformation of the rectangular (corresponding to relative ranks). However, in the two materialistic societies, it is necessary to specify the distribution of the valued cardinal good in order to obtain the PSO distribution. Thus, there can be many subtypes of the justice-materialistic and power-materialistic societies, depending on the distributional form of the valued cardinal good.

As discussed above, in seeking happiness, individuals may cycle over different combinations of PSOs, quantitative characteristics, and qualitative characteristics. At each turn of the sociobehavioral wheel, so to speak, a new identity is generated and a new magnitude of happiness. Societies, too, exhibit this dynamic, changing type as their members change.

Note that the old idea that good things come in threes – *omne trium perfectum* (everything that comes in threes is perfect) – is manifested twice in the NUT: in the three elements (quantitative characteristic, qualitative characteristic, and PSO) and in the three PSOs (justice, status, and power).

Subtypes of Materialistic Societies in the NUT: Distributional Form of Valued Cardinal Goods

To model a valued cardinal good X, a useful set of distributions includes distributions with different combinations of lower and upper bounds, such as distributions with and without a safety net and distributions with and without a maximum amount of X. Here we use three two-parameter continuous univariate distributions whose properties are well-known and which are widely used to model income distributions – the lognormal, Pareto, and power-function (Johnson et al., 1994, 1995; Kleiber and Kotz, 2003). Together this set includes some desired combinations. The Pareto combines a safety net with no maximum. The lognormal lacks an upper bound, like the Pareto, but, unlike the Pareto, it has no safety net. The power-function has a maximum but no safety net.

A further useful feature of this set is that the power-function includes as a special case the continuous uniform which represents a distribution of relative ranks. Thus, the same analysis that establishes results for quantitative Xs also provides results for justice-nonmaterialistic and power-nonmaterialistic societies.

Perhaps an even more important feature of this set of three modeling distributions is that one of the two parameters governs all measures of inequality (Jasso and Kotz, 2008). Thus, in a theoretical analysis of inequality using probability distributions it is not necessary to examine several measures of inequality, as all are monotonic functions of this one parameter, called the general inequality parameter.

While all five types of societies may have subtypes based on the number and associations among valued goods (and in the case of justice societies, the association between the actual reward and the comparison referent), only the two materialistic societies – justice-materialistic and power-materialistic – have subtypes based on the distributional form of the cardinal goods.

Table 1 provides the PSO distribution corresponding to the five types of societies and three subtypes each for the two

Table 1 PSO distributions in the five types of societies in the new unified theory of sociobehavioral forces, with cardinal good distributions ascribed in the two materialistic societies

Type of society/Distributional form of valued good in materialistic society	*PSO distribution*
1. Justice-nonmaterialistic	Positive exponential
2. Justice-materialistic	
Lognormal	Normal
Pareto	Negative exponential
Power-function	Positive exponential
3. Status	Negative exponential
4. Power-nonmaterialistic	Rectangular
5. Power-materialistic	
Lognormal	Lognormal
Pareto	Pareto
Power-function	Power-function

Note: The justice societies are for the special case in which the comparison referent is constant.

materialistic societies. The justice societies shown are for the special case in which the comparison referent X^* is a constant. As shown, the parsimonious setup yields seven distinct societal configurations of the PSO. In more elaborate cases – for example, justice societies in which X^* varies and/or societies which value multiple goods and the goods may be independent, negatively associated, or positively associated, many additional PSO distributions are generated, including both classical distributions such as the equal, Laplace, logistic, and Erlang and also new distributions such as the mirror-exponential obtained for the case of a status society with multiple negatively associated goods (Jasso and Kotz, 2007).

Distributions provide pictures of societies. This approach makes plain that societies – and their pictures – differ by the carrier of happiness and the number, distributional form, and associations of valued goods. For visualization, **Figure 2** provides graphs of the quantile function for an ordinal good and three cardinal goods (modeled by the lognormal, Pareto, and power-function distributions), as well as for the basic types and subtypes of societies to which they lead (shown in **Table 1**).

Subgroups – PreExisting and Emergent

Subgroups defined in terms of the personal qualitative characteristics introduced above are called *preexisting subgroups* because they are already formed before there is any sociobehavioral operation. Operation of the PSOs generates new subgroups – called *emergent subgroups* – which crosscut the preexisting subgroups. For example, operation of the justice PSO produces three emergent subgroups – consisting of individuals who are underrewarded, justly rewarded, and overrewarded – and these crosscut preexisting subgroups (such as those formed by race or gender).

When the group or population has a preexisting subgroup structure generated by a qualitative characteristic, each individual has access not only to the identity generated by his or her magnitude or relative rank in the quantitative characteristic – now called the Personal Identity – but also to a new identity called the Subgroup Identity and defined as the average of the Personal Identities within the preexisting subgroup (Jasso, 2008). The Personal Identity and the Subgroup Identity are used in several models, as discussed below.

Identity and Intersubgroup Relations

Consider a society with two preexisting subgroups. In this section we discuss two models that have been formulated. In the first model, everyone thinks and acts as a member of the subgroup. In the second model, each person seeks to maximize own happiness.

First Model – Homogeneous PreExisting Subgroups

Suppose that each person attaches to the Subgroup Identity – a sociological application of the Newtonian principle that mass accumulates at a point. Then relations between the two preexisting subgroups can be understood as the relation between the two Subgroup Identities. In particular, the social distance between the two preexisting subgroups can be defined as the difference between the two Subgroup Identities.

For a priori theoretical analysis, suppose that the two preexisting subgroups are nonoverlapping in the valued good (and hence in the PSO). If wealth is the valued good, the poorest person in the top subgroup is richer than the richest person in the bottom subgroup. We can then address classic sociological questions, including questions about the effect of the proportion in the disadvantaged group and the effect of wealth inequality.

Theoretical analysis yields two main initial results. First, the effect of the relative size of the two preexisting subgroups on the social distance between them varies considerably across the different societies. Expressed in terms of the proportion in the bottom subgroup, the effect on social distance may be increasing, decreasing, or nonmonotonic, depending on the PSO and the distributional form of the valued good. Second, in the materialistic societies, social distance always increases with inequality in the good's distribution. **Table 2** summarizes these results, and **Figure 3** provides visual illustration.

Second Model – Heterogeneous PreExisting Subgroups

Suppose now that persons seek to enhance their identity – by maximizing their PSO score. Equivalently, given that the PSO also generates happiness, suppose that persons seek to maximize their happiness. Then they will compare the Personal Identity with the Subgroup Identity (as discussed in Jasso, 2001b, 2008). If Personal Identity is higher than Subgroup Identity, they will ignore their subgroup and attach to the idea of themselves and others as individuals, blind to their own and others' subgroup origins. But if Personal Identity is lower than Subgroup Identity, they will attach to the subgroup and ignore their Personal Identity, finding the happiness they seek within their preexisting subgroup.

In a society with two subgroups, this identity enhancing process will yield three new emergent subgroups – persons from preexisting subgroup A who attach to A, persons from preexisting subgroup B who attach to B, and persons from both preexisting subgroups who attach to self. Persons in the first two of the new subgroups are called Subgroupistas, persons in the third are called Selfistas.

To illustrate, **Figure 4** provides graphs of the status PSO in four hypothetical societies, each with two preexisting subgroups such that the preexisting subgroups are nonoverlapping in status (and in whatever whatever personal quantitative characteristic generated status). The four groups differ in the subgroup split, that is, the proportions in the two preexisting subgroups, ranging from a group in which the bottom preexisting subgroup has 25% of the population and the top preexisting subgroup has 75% to a group in which the bottom preexisting subgroup has 75% of the population and the top preexisting subgroup has 25%. A vertical line divides the two preexisting subgroups. The curve in each plot depicts Personal Identity – i.e., each individual's own status score. The long horizontal line represents the average status for the whole group, and the two smaller horizontal lines represent the average status for the two preexisting subgroups, that is, the Subgroup Identity. The intersection of the status curve and the Subgroup Identity marks the point at which Personal Identity equals Subgroup Identity. Regardless of the subgroup split, each preexisting subgroup has both Selfistas (the subset to the right of the intersection) and Subgroupistas (the subset to the left of the

Figure 2 Quantile function of PSO distributions arising from valued goods, with cardinal goods modeled by three variates: single-good case. The distributions of the valued goods are in the .0 column and the PSO distributions in the .1, .2, and .3 columns. The justice PSO distribution is in the .1 column, the status PSO distribution in the .2 column, and the power PSO distribution in the .3 column. The justice PSO distributions pertain to the case where the comparison referent X^* is constant. All the graphs include a horizontal line at the arithmetic mean.

Table 2 Effect of proportion in the disadvantaged subgroup on social distance, in the five types of societies in the new unified theory of sociobehavioral forces, with cardinal good distributions ascribed in the two materialistic societies

Type of society/Distributional form of valued good in materialistic society	*As proportion in disadvantaged subgroup increases, social distance …*
1. Justice-nonmaterialistic	Decreases
2. Justice-materialistic	
Lognormal	Decreases, then increases, in symmetric U
Pareto	Increases
Power-function	Decreases
3. Status	Increases
4. Power-nonmaterialistic	Is constant
5. Power-materialistic	
Lognormal	Increases
Pareto	Increases
Power-function	Decreases

Notes: The justice societies are for the special case in which the comparison referent is constant. In the materialistic societies, social distance increases with the cardinal good's inequality.

intersection). Thus, it is always the case that the richest or most beautiful or most accomplished in each preexisting subgroup will be Selfistas, while the poorest or least beautiful or least accomplished will be Subgroupistas. This in turn suggests that 'the best and the brightest' in each preexisting subgroup cannot be trusted with important work for the preexisting subgroups.

In an application to residential segregation, this identity enhancement model predicts three emergent subgroups: (1) members of the bottom subgroup who are segregationist; (2) members of the top subgroup who are segregationist; and (3) members of both subgroups who are blind to their subgroups and thus integrationist. In the special case of blacks and whites, the model predicts three types of neighborhoods: (1) all-black; (2) all-white; and (3) mixed.

New quantities arise, adding to the proportions in the three main emergent subgroups the following: (1) proportions black and white among integrationists and among segregationists; and (2) proportions integrationist and segregationist among blacks and among whites.

It will be no surprise to learn that the NUT gives rise to a dazzling diversity of societies, with intricately differing configurations of all the quantities. The exact outcomes depend not only on the proportions in the preexisting subgroups, as in Figure 4, but also on the configuration of (1) the active PSO, (2) the number and associations among the valued goods, and (3) in the two materialistic societies, the distributional form of valued cardinal goods (Jasso, 2008). For example, in a status society the proportion integrationist is always less than half (both in the overall society and in each preexisting subgroup), but in a justice-nonmaterialistic society the proportion integrationist is always more than half (again both in the overall society and in each preexisting subgroup).

In sum, the new unified theory of sociobehavioral forces leads to five types of societies – consistent with Plato's intuition – two of these spawning subtypes. This parsimonious beginning generates a wide variety of outcomes. The seemingly mysterious effects of subgroup relative size on social distance,

Figure 3 Social distance in justice, status, and power societies, with differing configurations of valued goods and goods' distributional forms, by subgroup split *p*. The letters J, S, and P denote the justice, status, and power societies, respectively. In the three cardinal-good societies, the greater the inequality in the good's distribution, the greater the social distance (and the higher the vertical placement of the curve). now increasing, now decreasing, the similarly mysterious configurations of segregationists and integrationists, all may be the orderly consequence of a few basic principles.

Types of Societies in the Deeper-Forces Model

Suppose that justice, status, and power – the engines of the NUT – are not the most fundamental forces generating human behavior. Suppose they are themselves generated by deeper forces, deeper carriers of happiness. This section briefly considers four candidates for deeper forces discussed in Jasso (2001a, pp. 350–352):

- to know the causes of things
- to judge the goodness of things
- to be perfect
- to be free

The first candidate-force is rooted in the individual's thirst for reliable knowledge about the nature of the world, a thirst for knowledge visible in the earliest pages of Genesis, in the history of philosophy and science, in a variety of 'descriptive' and 'positive' activities, and in people's everyday lives. For example, Virgil writes in the *Georgics* (II, 1, 490), "Felix cui potuit rerum cognoscere causas" ("Happy the person who could search out the causes of things"). It leads to what may be called a Science Society.

The second candidate-force pertains to the individual's drive to judge, to discern what is good and what is bad; it is visible in a variety of 'prescriptive' and 'normative' activities and, like the first candidate-force, in people's everyday lives. It leads to what may be called a Philosophy Society.

The third candidate-force reflects the individual's quest for perfection. As Aquinas (*Summa Theologica*, II, Part I, Q.5) put it, "Humans seek their own perfection." They desire "a well-disposed body" and "keenness of wit and beauty of body" (Aquinas, *ST* II, I, 4). Or as an American teenager describes her ballet classes at the Bolshoi, "I love how strict they are, how every movement is towards perfection" (Milzoff, 2014). Of course, it is difficult, often impossible, to alter the endowments dealt by nature and it may take long and arduous years to augment material possessions. Yet this seeking after perfection does not result in universal sorrow, for humans possess a faculty for achieving *the illusion of perfection*. There are two pathways: (1) find a combination of valued good and group such that the individual ranks at the top, or (2) acquire large holdings of cardinal goods. This quest for perfection, too, is visible in several literatures dating back to classical antiquity. Adkins (1972) provides valuable discussion of the human obsession with the competitive excellences, first documented among the Greeks. The quest for perfection becomes explicit in the *Confessions* of Augustine, the *Autobiography* and *Spiritual Exercises* of Ignatius of Loyola, and the *Way of Perfection* of Teresa of Avila. And it permeates Cervantes' *Don Quijote*. Cervantes, ever keen on human nature, comments often on this *issimus* phenomenon; for example, he has Don Quijote set out to become the best knight-errant and Sancho the best squire-to-a-knight-errant that ever lived. This candidate-force leads to what may be called a Perfection Society.

The fourth candidate-force – to be free – also appears since antiquity, for example, in Epictetus (1983). And it becomes a rallying cry in more recent centuries. It leads to what may be called a Freedom Society.

If each society had a single engine, this setup would give rise to four types of societies. But one can easily imagine societies with multiple engines – for example, societies which care about both Science and Philosophy, or both Science and Freedom. Having dual engines produces six new types of societies, triple engines spawns four more types, and finally there is one quad-engine society – for a total of 15. If one adds the null case – with none of the four engines – the total comes to 16 (that is, 2^n).

This four-engine model is in its infancy. Future theoretical development might explore the conditions under which one or another type of society would be realized, and it might derive testable predictions, including novel predictions. For now it is possible to suggest that the goods in the NUT reflect the perfection engine, that the comparison referent reflects the judgment engine. Empirically, factorial survey methods for studying beliefs and judgments provide ways to assess operation of the first and second candidate-forces, respectively.

Afterword

As Aristotle (*Nicomachean Ethics*, Book 1, Chapter 7) observed, "One swallow does not make a summer, nor does one day; and so too one day, or a short time, does not make a man blessed and happy." Societies may cycle over different types, as their members switch active carriers of happiness or valued goods or the goods change distributional form. The history of a group or population may be written in their members' time series of carriers of happiness and the ensuing time series of types of societies.

Society and People: History of the Concept

Lars Trägårdh, Ersta Sköndal University College, Stockholm, Sweden

© 2015 Elsevier Ltd. All rights reserved.

Abstract

'People' is a concept that has come to acquire two related, yet different, meanings. On the one hand, there is the democratic, political conception of 'the people' – the people as *demos* – and on the other there is the ethnic, cultural conception of 'a people' – the people as *ethnos*. In either sense of the word, the crystallization of the modern concept of the people can be traced back to the later part of the eighteenth century, when the idea of the 'sovereignty of the people' became central to democratic political theory and the nation-state emerged as the paradigmatic form of state institution, informed by the principle that ideally each state contained one nation/people, and that each nation/people constituted one state. In this article each meaning will be discussed, as well as their relationship to each other.

'People' is a concept that has come to acquire two related, yet different meanings. On the one hand, there is the democratic, political conception of 'the people' – the people as *demos* – and on the other there is the ethnic, cultural conception of 'a people' – the people as *ethnos*. In either sense of the word, the crystallization of the modern concept of the people can be traced back to the later part of the eighteenth century when the idea of the 'sovereignty of the people' became central to democratic political theory, and the nation-state emerged as the paradigmatic form of state institution, informed by the principle that ideally each state contained one nation/people, and that each nation/people constituted one state. In this article each meaning will be discussed, as well as their relationship to each other.

The 'People' and the Democratic and National Imaginaries

Prior to the eighteenth century the concept of the people was of relatively minor importance. Present from the outset were two basic meanings of the term, a general one, closely related to 'nation,' 'community,' and ' society,' and a particular one, which opposed the people to the elite. Take, for example, Samuel Johnson's *A Dictionary of the English Language* from 1755, which juxtaposes the following definitions: (1) "A Nation, those who compose a community," (2) "The Vulgar," and (3) "The Commonality; not the princes or nobles." Similarly, Abbé Fuertière's *Dictionaire universel* from 1690 lists both a positive, general meaning – "the mass of persons who live in one country, who compose a nation" – and a negative one, defined "by opposition to those who are noble, wealthy, and educated."

During the eighteenth century the concept, which until then had carried largely negative connotations, associated with the vulgar, the lowly, and the beastly – what the Romans referred to as *plebs* – underwent a dramatic change, and 'the people' was valorized and reformulated in distinctly positive terms, as the source of mortal virtue, political legitimacy, and cultural authenticity, a sentiment captured in the increasingly common saying, "the voice of the people is the voice of God." By around 1800 the 'people' was thus constituted as what Reinhart Koselleck calls a 'key-concept' (see Brunner et al. 1972–92). In dictionaries published after 1800 a veritable explosion of neologisms derived from the root words 'people,' '*Volk*,' '*peuple*,' '*narod*,' 'folk,' and so on, can be observed, reflecting what has been called the 'discovery of the people' (Burke, 1994).

This production of new words had two origins. On the one hand, there were the terms derived from the vocabulary of the English, French, and American revolutions, to which the principle of the 'sovereignty of the people' was the central tenet. In opposition to the Old Regime, with its feudal, hierarchical society with the sovereign king at the top of the social and legal pyramid, a new idiom was elaborated that spoke in terms of citizenship, civil liberties, and legal equality. In England the primacy of Parliament and especially the House of Commons gave expression to this new political reality, which also brought with it a new sense of common, popular English nationality. In France the Third Estate – which contained the now celebrated people – became synonymous with the nation, while the nobility was excluded from such membership, associated, as Abbé Sieyès (3 May 1748 to 20 June 1836) put it, with 'incurable idleness,' 'collapse of morality,' and a variety of exclusive and insulting social and political rights, privileges, and prerogatives. And in the United States, the Declaration of Independence spoke of the rights of 'we the people' to assert its sovereignty against the tyrannical and illegitimate powers of the English king.

On the other hand, there were Romantic, ethnographic terms inspired by the German philosopher Johann Gottfried von Herder (25 August 1744 to 18 December 1803) and his followers who ventured into the countryside to explore the very popular culture that hitherto had been the objects of scorn and contempt. In 1774 Herder coined the word *Volkslied*, or 'folksong,' as the title of a collection of songs he published, and a host of similar words pertaining to 'folklore' and popular culture soon became commonplace in most European languages. As in the realm of politics, 'the people' in this ethnographic sense was now to be rescued from oblivion and condescension and instead to be presented as the authentic bearer of national culture. True poetry, Herder suggested, gives expression to the 'soul of the people,' and according to Jacob Grimm (4 January 1785 to 20 September 1863) such authentic, national poems 'belong to the whole people.' For Herder, the

people was first and foremost a matter of history and culture, and he harbored an organic vision of the concept. Each people was thus conceived as a collective individual that possessed its own national character, its own language, its own mores, its own morality, and its own sense of self. In contrast to the political definition of the people as demos, Herder thus stood in the forefront on an elaboration of the people as ethnos. Indeed, Herder tended to perceive the emerging modern state with a great deal of suspicion, as a 'machine,' an 'artificial form of society' that threatens the organic, authentic culture of a people.

From a wider perspective these new terms belonged to a more general phenomenon of linguistic innovation during this period. As Lynn Hunt has observed in the context of the French revolution, 'words came in torrents' as the old political, social, and economic order broke down and attempts were made to semantically capture a new one (Hunt, 1984). As the rate of change accelerated, experience could no longer guide action in the present. A new interpretative language was required to make sense of the world. Thus attempts had to be made to formulate a vocabulary that no longer simply referred to what Koselleck calls 'the space of experience,' but instead reached into the future, creating a 'horizon of expectation,' terms through which prognostic political goals could be hatched (Koselleck, 1985). In other words, the concept of 'the people' acquired a utopian character. As such it came to occupy a central position in the 'democratic imaginary' (Joyce, 1994), as a concept that did not merely serve to describe an existing state of affairs, but also prefigured the future. By elaborating visions of popular sovereignty, a politically potent expectation was created that has come to define the context for politics ever since. Similarly, the people imagined as a form of community – the nation – was a vision that came to inform European and global politics as nationalism became a fundamental political force, erupting in the revolutions of 1848 – 'the springtime of the peoples' – in the unification of Italy and Germany, in the collapse of the Hapsburg Empire after World War I (WWI) in the shadow of President Woodrow Wilson's (28 December 1856–3 February 1924) ideology of the right to national self-determination, and in the politics of anticolonial national liberation movements during most of the twentieth century.

Structural Relations: Who Belongs to the People?

In structural terms, the difference between these two conceptions is one of how membership in 'the people' is delimited. In one case, the inclusion/exclusion is made in inside/outside terms. Here the emphasis is on setting limits against other peoples by defining the peculiar character of one's own people and culture in relation to those of others. One way is to define the people in terms of race and blood, and to determine citizenship according to the strictures of *jus sanguinis*. In its most extreme and lethal form, this logic underpinned the politics of national belonging practiced by the National Socialists in Hitler's Germany, but it has also been a basic legal principle for acquiring automatic citizenship in many other countries. Alternatively, membership may be determined through participation in what Jean Jacques Rousseau (28 June 1712–2 July 1778) called 'civil religion,' allegiance to a national constitution and to the law, a process by which individuals become active citizens, devoted to the nation, and to the practice of civic virtue. In this context, ethnicity tends to play a less defining role, and rights to citizenship may, as in France or the United States, be conferred automatically on anyone born in the country (*jus soli*) (Brubaker, 1992). In either case, citizenship and nationhood is by definition simultaneously a matter of inclusion and exclusion, however benign and civic the criteria for membership in the national community may be. Thus the imagined community of the people/nation is always both sovereign and limited, surrounded by and defined against other 'peoples' who likewise are bounded and sovereign within those boundaries (Anderson, 1983).

This emphasis on the people as a community built on affective ties of solidarity and comradeship, furthermore, requires a minimum of cultural if not ethnic homogeneity, and thus nation-states have consistently engaged in efforts at 'nationalizing the masses' through public institutions such as the schools and the military, creating a nationally minded people where there previously existed diverse and culturally heterogeneous populations, divided by all manner of differences in language, custom, and law, turning 'peasants into Frenchmen,' as the historian Eugen Weber memorably put it in the case of France (Hobsbawm and Ranger, 1983; Mosse, 1975; Weber, 1976).

In the other case, associated with the democratic definition of the people, the delimitation is made along a vertical axis where 'the people' is set against segments of the population at large that are defined as not belonging to the people. This can be done by excluding groups either at the top or the bottom. So, for example, the people can be defined as the entire population except the government, or the broad segments of the population versus the ruling elite. One expression of this democratic and 'from below' definition of the people found expression in the political movements called 'populism' that took form in, for example, the United States toward the end of the nineteenth century (Goodwyn, 1976). It has also been done by excluding groups at the bottom. Thus, to take the German case, the working class could be seen *vaterlandslose Gesellen* – as lacking a sense of 'fatherland' – whose primary identification was with the international proletariat and not with the German nation. The words *Pöbel* (from French *peuple*) and *Masse* were deployed in similar ways, to distinguish the 'real,' respectable *Volk* from the degenerate, urban underclass. Indeed, the delimitation could be made in both directions simultaneously; the Social Democrats, for example, could claim the noble title of the *Volk* defined against both the capitalist elites above and the *Lumpenproletariat* below.

In the socialist vocabulary, the concept of the people had to compete with related notions that figured prominently in the Marxist idiom, particularly 'class' and 'proletariat,' especially since it was often closely linked to the concept of the 'nation,' an idea that sat uneasily within Marxist theory. Eventually, however, 'the people' retained a largely positive status, as evidenced in the common usage of the concept of 'the people's republic' in referring to a variety of communist regimes. In the context of the liberal democratic political system of the West, the utopian impulse at the heart of the democratic definition of the people, one that envisions not only the sovereignty of the people but also that all individuals within a sovereign state

should belong to the people/*demos*, has led, at least in theory, to an increasing democratization of society and to the abolition of traditional obstacles to citizenship on the basis of categories such as class, creed, race, or gender.

National Variations: Neighboring Concepts and Political Ramifications

While the concept of the people has played a central role throughout the Western world and beyond, the impact of this key concept has varied considerably from country to country. This is true both when it comes to the specific political impact and how the 'people' came to be understood in relation to neighboring key concepts such as state, society, community, class, proletariat, and individual rights and liberties.

In the French case, the ideas of the people and the nation became strongly linked to the state and the political notion of the general will. Thus the French nineteenth-century historian Jules Michelet (21 August 1798 to 9 February 1874), in his influential book *Le Peuple* (1846), focused on the role of the Revolution and democratic politics as constitutive of the people/nation, and similarly Ernest Renan (28 February 1823 to 2 October 1892), in his essay, "What is a Nation" (1882), emphasized that the nation should not be seen as first and foremost a matter of blood, but as an expression of political will, 'a daily plebiscite.' As Renan put it, when it comes to nationality, "the people's wish is after all the only justifiable criterion, to which we must always come back." Here Renan was significantly arguing against fellow German historians over the status of Alsace-Lorraine, the provinces that lay in the borderland separating Germany from France, an area annexed by the Germans in the wake of the Franco-Prussian war of 1870.

By contrast, the German conception of the *Volk* and the nation was, pace Herder, at heart a cultural conception that at best saw the state as a protective shell safeguarding the Volk/nation, or, as in the case of Herder himself, saw the state as an artificial and even destructive form of society. At the same time, the French and the German conceptualizations of the people were similar in that they both were collectivist. *Le peuple* and *das Volk* were both formulations that suggested a collective, be it a national, ethnically/culturally defined community, or a collectivity that expressed the democratic, general will of the people.

In England the idea of the people came, as in France, to be strongly associated with political institutions and practices. However, whereas in France the idea of the people/nation tended to be associated with the collective, communal notion of the general will, which gave priority to the nation and to the social over the rights of the individual, in England it was more strongly associated with the assertion of parliamentary power, individual liberty, and the limitation of state power. Thus English national identity itself came to be linked to political as well as economic liberalism, and to a conception of the general good that took as the basic unit the freeborn individual Englishman.

These tendencies were even more fully realized in the United States, where the separation of powers and the protection of individual rights were enshrined in the constitution itself. The starting point was the stress on the American colonists' entitlement to "English liberties" and civil rights, rights that, it was claimed, had been trampled upon. The next step was to separate from this close association to Englishness and instead to refer, as was done in the Declaration of Independence, to the 'inalienable rights' ultimately grounded in universal natural law and 'the rights of man.' However, in spite of this emphasis on universality, the Constitution – and the rights and liberties it guaranteed – soon became the basis for the elaboration of an American civic nationalism, based on the idea that the American people, formed by its liberal democratic institutions, was exceptional in its commitment to individual liberty and equality. Thus in the United States, the idea of 'We the People' as the ultimate source of legitimacy and sovereignty was informed by a pervasive individualism and an enduring suspicion of centralized government. If in the French case the primacy of the people as a unified collectivity went hand in hand with strong central government, national standards, and a distaste for local difference, it was conversely true that in the US case the primacy of the people as a collection of free individuals informed an opposite tendency.

At the same time, Herderian notions of national character also came to infuse US self-understanding of the essential character of the American people, which revolved around the idea that America as a people and a nation was more mature and evolved than other peoples by virtue of its deep-seated capacity for democratic self-government. A similar fusion of an ethnic and a civic notion of the people occurred in Sweden, where leading Social Democrats after WWI came to embrace the idea that Swedes were endowed with a peculiar propensity for democracy and freedom, amounting to what one of them referred to as having 'democracy in the blood.' Citing a long, unbroken legacy of self-government that linked modern-day Swedes to the ancient yeoman peasants, the existence of a tradition was claimed, in which "democracy is rooted not merely in the constitution, but also in our traditions and in the disposition of the folk," as the Swedish prime minister Per Albin Hansson (28 October 1885 to 6 October 1946) put it in 1935.

On this basis, Swedish Social Democrats conjured up a vision of a *folkhem*, a people's home, which usefully can be contrasted with the contemporary German slogan, *Volksgemeinschaft*, or 'people's community,' championed by Hitler and the National Socialists. While both concepts celebrate national community, one prefigured the Nazi racial state, while the other became the organizing slogan for the Swedish welfare state. In the Swedish case, the concept of the *folk* connoted democratic sentiment rooted in a particular, common history; in the German one, the corresponding concept of the *Volk* referred to a racial community. This is particularly clear in the adjectival forms of *folk*/*Volk*, both equally difficult to translate into English. The German word, *völkisch*, means 'national' but with a distinct emphasis on race, and specifically with an anti-Semitic thrust. The Swedish word, *folklig*, conversely, is better translated as 'popular/populist/democratic,' with an association to the democratic legitimacy of claims made by those who credibly speak in the name of 'the people,' first and foremost the nonelite, that is, workers and peasants.

Thus the precise relationship between the concept of the people and such neighboring concepts as state, society, culture,

race, and the individual become absolutely central if we are to understand the political implications of the concept of the people. In one case, the proximity of *Volk*/nation/culture/race/collectivism is associated with racist nationalism; in another, the linkage between *peuple*/nation/state/society connotes a collectivist, if democratic, conception of popular sovereignty; in a third, the association with the people/individual liberty suggests a liberal and individual rights-based political order; while in a fourth one, the correlation of folk/home/solidarity/state informs the vision of a welfare state.

Cosmopolitanism, Human Rights, and the Contradictions of National Democracy

The tension between the idea of the people as nation (*ethnos*) and the people as the key concept in the democratic imaginary (*demos*) was, as we have seen, always present. Few, if any, actually existing nation-states have lived up to the ideal type that demanded, first, one people/nation in each state and, second, a state for each people/nation. During the nineteenth and early twentieth centuries these tensions were, however, partially masked by the emancipatory process of democratization within nation-states and the projects of national liberation in the remaining multinational empires, which overshadowed and obscured the continued and unresolved challenges when it came to reconciling nationalist and democratic claims, not least those related to the presence of ethnic minorities.

The embrace of the ideas of the people and the nation reached a high point with the outbreak of WWI and the subsequent postwar settlements. On the one hand, the 'Spirit of 1914' marked the victory of nationalist sentiments over class solidarity as German and French workers marched to war rather than joining hands under the red banner of the Second International. On the other hand, the American President Wilson's '14 points' and his related declaration of the 'right to national self-determination' at the end of WWI explicitly joined the projects of democratization and national liberation and unification under one grand vision. This resulted in a number of postwar readjustment of borders according to those principles as well as to the establishment of the League of Nations.

The idea of each people's right to self-determination would live on after World War II (WWII) during the era of national liberation movements in Africa and Asia. However, the horrors of the Holocaust and WWII produced in Europe a revulsion against ethnic nationalism that led to an embrace of trans- or postnational ideals, ranging from the establishment of the United Nations (UN) in 1945 and a number of institutions and declarations associated with the mission and ethos of the UN, such as the Declaration of Human Rights in 1948, to regional efforts to counternationalism and preempt future wars, most prominently the establishment of what over time became the European Union. In both cases, we can trace back the foundational ideas to the same historical period that spawned the concepts of the people and the birth of modern nationalism. While Herder and Rousseau can be seen as the founders of ethnic and civic nationalism, Immanuel Kant (22 April 1724 to 12 February 1804) can be viewed as the forefather of modern cosmopolitan ideas that reject the centrality of peoples and nations in favor of a vision that centers on the idea of one world and one humanity. In his essay "Toward Perpetual Peace," Kant thus proposes a *jus cosmopoliticum* (cosmopolitan law/right) with respect to "the right to the earth's surface which belongs to the human race in common," the realization of which could "finally bring the human race ever closer to a cosmopolitan constitution" (Kant, 1999: 8: 358).

In practice, the pitting of universal and cosmopolitan ideals against that of people and nation played itself out against the enduring presence of the nation-state in the context of increasing globalization. Globalization happened, first and foremost, in the economic arena, symbolized by institutions like the World Trade Organization, the World Bank, and the International Monetary Fund. But the more far-reaching Kantian ideals lived on as well, not least in the continued growth of human rights as field for both academic work and political activism, marked by, for example, the near-universal adoption of the UN Convention of the Rights of the Child in 1989 and the creation of the International Criminal Court in 2002 (Beck, 2006). However, the nation-state and the idea of the people and national identity and community did not disappear but instead entered a new phase in the early 1990s, fueled partly by populist reactions to elite cosmopolitanism and increased migration.

Thus the fluid movement between the two conceptions of the people again came to the fore during the famous Monday demonstrations in Leipzig, East Germany, during 1989–1990 as the Berlin Wall came down and the process leading to German unification unfolded. The crowds would almost seamlessly shift from a democratic chant "*Wir sind das Volk*" (we are the people) to the national slogan "*Wir sind ein Volk*" (we are one people). Already at that time, especially given recent German history, this blending of the national and ethnic with the democratic created anxiety, prompting political leaders like Helmut Kohl in Germany to call for Germans to imagine themselves as much as Europeans as Germans. But it soon became clear that the particular German inflection of this (con)fusing of the two concepts of the people was simply one example of the much broader problem of how to reconcile the ideals of national citizenship with cosmopolitan notions such as human rights. Neonationalism led to the breakup of not only the Soviet Union but also of Yugoslavia and Czechoslovakia. And by the late twentieth and early twenty-first centuries the tensions between demos and ethnos became harder and harder to ignore throughout Europe where European integration fueled more rapid migration within the European Union at the same time as globalization in the context of large gaps in wealth and stability exposed the European countries to an increasing inflow of political and economic refugees from the global south.

Since both national community and democratic citizenship historically were linked to the emerging global dominance of the nation-state, and fundamentally rested on boundaries that excluded at the very same time as they included, the increased volume and speed of migration have tended to expose what scholars refer to as the 'paradoxes' or 'contradictions' of (national) democracy. Thus Seyla Benhabib (2004) argues that national democracies are intrinsically exclusionary since they offer full rights and privileges only to members, i.e., citizens. This is so in spite of the fact that they internally speak in

a universalist language rooted in notions of equal democratic rights. However, this is a bounded universalism that distinguishes between national citizens and universal personhood (Bosniak, 2006).

This structural contradiction of national democracy comes to a head in the context of migration where it translates into differential treatment of persons on the basis of legal rules shot through with political and moral claims expressing the persistence of racialized hierarchies and notions of ethnic cultural membership (Barker, 2013). Migration, illegal as well as legal, and the attempts by the European Union and its member states to stem the flow and reassert boundaries has led both to concrete misery in the form of brutal border controls, detentions, and deportations of 'aliens,' and to a moral and political crisis as the contradictions between universal moral rules founded in notions of human rights and nationally bounded claims derived from the idea of citizenship in particular nation-states became ever more clear.

Conceptually, we are back, then, to competing moral and political ideals that had been formulated as early as the late eighteenth century. On the one hand, there is Immanuel Kant's cosmopolitan vision of perpetual peace, and on the other hand the twin conceptions of the primacy of the people in the form of national democracies in which all power emanated from the sovereign peoples in their hybrid ethnic/civic form. The Kantian conceptions have found new life after the murderous destruction of the WWII, expressed institutionally, morally, and legally in the UN, the international courts, and in declarations about human rights. At the same time, these dreams of transcending the bounded communities of the nation-states have run up against a resurgent neonationalism coming from both right-wing movements that emphasize ethnic national identity in the idioms of blood and belong, and from national democrats who embrace a welfare state nationalism that continues to speak in a universal civic language that extolls demos even as it reasserts the right of each nation-state to control its border. Here the neonationalist parties, particularly in welfare states like the Netherlands, the Nordic countries, France, and Britain, have been able to exploit a political vacuum created by the postnational turn of the established left-wing parties. These parties often acquire some of the rhetoric of national community that from the outset was part of the social democratic welfare state projects, resulting in a welfare state nationalism with more explicit ethnic overtones combined with a defense of values such as democracy, gender equality, and gay rights against the supposed threats of encroaching foreign values and practices associated with migrants, especially Muslims. Furthermore, this embrace of the key concept of 'people' and 'nation' by the neonationalist parties exploits a gap between cosmopolitan elites more focused on human rights and national-minded populations that seek refuge and protection in the name of national community. The old term 'populism,' earlier associated with popular and democratic aspirations, thus becomes a wholly negative term for these elites, who identify it with racist and xenophobic nationalism. This also exposes a fundamental challenge for neo-Kantian supporters of a cosmopolitan one-world vision: globalization so far has been dominated by a neoliberal approach that lacks the democratic and most particularly the solidaristic element of the politics of national community that produced the welfare states.

Sociobiology and Sociology: A New Synthesis

Abstract

Sociobiology is the study of the biological basis of social behavior among animals and humans. In recent years, sociologists have begun incorporating key ideas and explanatory principles from sociobiology into sociology. This has resulted in criticism of the tabula rasa model of the human mind and its replacement by the adapted mind model. Evolutionary sociologists have proposed new explanations of the evolutionary origins of human sociality and societies, and they have applied evolutionary principles to the study of social behaviors including mating and reproduction, gender and gender inequality, social capital, and dominance and social inequality.

Although sociology was influenced by the Darwinian revolution, by the early to mid-twentieth century it had, for the most part, distanced itself from the life sciences, including evolutionary biology. In 1975, the evolutionary biologist and myrmecologist E.O. Wilson published *Sociobiology: The New Synthesis*, thereby setting the stage for an eventual reunion between sociology and evolutionary biology. By the 1990s, some sociologists had begun calling themselves evolutionary sociologists, and their work was informed by various branches of behavioral biology including, but not limited to, sociobiology, behavioral ecology, the neurosciences, population genetics, and ethology. In addition, the recent emergence of evolutionary psychology also influenced the development of the new evolutionary sociology. By 2004, the community of evolutionary sociologists in the United States had become sufficiently large to enable them to form a section of the American Sociological Association that is now called 'Evolution, Biology and Society.' This article reviews key aspects of sociobiology that contributed to the development of evolutionary sociology as it manifests itself in the early twenty-first century.

Evolution of Social Behavior by Natural Selection

Sociobiology is the study of the biological basis of social behavior among animals, including humans (Wilson, 1975). The key concepts and explanatory principles comprising sociobiological thought derive from neo-Darwinian evolutionary theory, the integration of Darwin's theory of evolution by natural selection and Mendelian genetics. Neo-Darwinian theory analyzes the traits of organisms as possible evolved adaptations. An adaptation is a phenotypic trait that evolves by natural selection and contributes to an organism's chances of survival and reproductive success. Evolved adaptations include morphological traits, physiological traits, and behavioral traits, including social behavior. Natural selection itself occurs as environmental forces such as predation, disease, climate change, and competition result in variable reproductive rates among individuals and thus, in differential gene distributions within populations over generational time. Thus, organisms are said to vary in fitness as their reproduction rates vary, thereby contributing to changes in gene (allele) frequencies over time. Evolutionary biologists distinguish between two types of fitness. Individual (or Darwinian) fitness refers to an individual organism's transmission of genes by producing offspring. Inclusive fitness refers to the combination of an organism's individual fitness and its influence on the fitness of biological kin other than its direct descendants. Simply put, there are two ways that an organism can gain genetic representation in future generations: (1) it can reproduce and (2) it can contribute to the reproductive success of close kin, a process called kin selection in evolutionary biology.

In addition to natural selection, sexual selection is an important evolutionary process, especially in terms of its influence on social behavior. Sexual selection occurs when evolved traits influence the ability of an organism to recruit a mate and produce offspring. For example, brightly colored plumage among some species of birds serves as an attractant to females, thereby enabling males that display the brightest coloration to reproduce more successfully than males with duller color patterns. Brightly colored plumage can be an indicator of a robust immune system, a trait that is likely to be favored (unconsciously) by females that are inspecting males for potential mates. Similarly, males may be adapted to express preferences for cues that signal potential high fertility among females, thereby courting such females more vigorously than other females.

An important topic in sociobiological inquiry is the problem of altruism. In evolutionary theory, altruism refers to any trait, the possession of which reduces the fitness of the individual bearing it while, simultaneously, increasing the fitness of another individual. As W.D. Hamilton (1964) explained, however, altruism can be more apparent than real. For example, if the sacrificial behavior of one individual reduces its fitness to zero (by sacrificing its life) and thereby saves the life of another, unrelated individual, an evolutionary biologist would identify such behavior as altruistic. However, if the recipient of the apparent altruist's beneficence was a biological relative, then the behavior would be viewed as phenotypically altruistic but genetically selfish. That is, by losing its life, the individual performing the sacrifice saved the life of a relative with whom it shared genes (alleles), thereby contributing to the survival of copies (replicas) of its own genes

 http://dx.doi.org/10.1016/B978-0-08-097086-8.32010-4

present in the body of its relative. Thus, altruism can evolve by kin selection.

Natural selection can also produce another variant of altruism that is more apparent than real, and it is called reciprocal altruism (Trivers, 1971). If an individual behaves in a manner that reduces its own fitness and increases the fitness of a nonrelative, it is behaving altruistically. However, if in the future the recipient of the altruistic behavior reciprocates and behaves altruistically toward its benefactor, then the original act of altruism is better viewed as the first stage in a process of delayed reciprocity, which evolutionary biologists call reciprocal altruism. A recent review of research on reciprocal altruism revealed that, with a few exceptions, it is rare among nonhuman species, and that it appears that humans are without rival as the premier reciprocal altruists (Clutton-Brock, 2009).

In addition to altruism (and reciprocal altruism), sociobiologists investigate other forms of social interaction, including mutualism, commensalism, and social parasitism. In mutualism, both parties in a relationship receive benefits from the interaction. In commensalism, one party benefits, but the other neither receives a benefit nor incurs a cost. In social parasitism, one party extracts a benefit at the expense of the other party. These concepts have value for evolutionary sociological analysis. For example, Cohen and Machalek (1988) have adapted models of social parasitism that were developed for studying nonhuman social species in order to analyze patterns of expropriative crime among humans.

Until very recently, Hamilton's notions of kin selection and inclusive fitness constituted a largely unchallenged explanation of most patterns of cooperative social behavior among animals. The discovery that genetic relatedness is the bedrock on which many forms of cooperative group life are based was elucidated in Hamilton's analysis of the role of genetics in supporting highly cooperative societies of eusocial insects (ants, bees, and wasps, but not termites). Because ants, bees, and wasps feature a distinct form of genetics called haplodiploidy, the females are hyperrelated to each other, and it is to this hyperrelatedness that Hamilton and later others attributed the highly cooperative and cohesive social systems comprising colonies of ants, wasps, and bees. Specifically, males in these taxa develop from unfertilized eggs and inherit only one set of chromosomes (from their mother), while females inherit one compliment of chromosomes from their mother and a second compliment from their father. Consequently, full sisters are more closely related to each other ($r = 0.75$) than each is to her mother ($r = 0.5$). Hyperrelatedness among sisters means that they share, on average, 75% of their genes with each other, thereby creating a situation whereby there is a 25% greater coincidence of their genetic interests than there is among full siblings in diploid species, which share, on average, only 50% of their genes. In Hamilton's view (and according to what has essentially become orthodoxy in conventional sociobiology), the forces of kin selection are particularly strong among haplodiploid species, thereby explaining the great degree and complexity of social life among the eusocial insects.

Recently, however, E.O. Wilson and D.S. Wilson have challenged the sociobiological orthodoxy that kin selection and inclusive fitness explain eusociality among ants, bees, and wasps. Furthermore, they contend that kin selection cannot explain the highly evolved form of eusociality evident among termites, because termites are diploid. Thus, instead of attributing the basis of eusociality to the unusual genetics of haplodiploidy, Wilson and Wilson turn to an ecological explanation in which they argue that patterns of social life among ants, bees, wasps, and even termites more likely evolved as a response to a circumstance whereby members of a group occupy a defensible residence (such as a nest), live in reasonably close proximity to a food source, and provision their young (Wilson, 2008; Wilson and Wilson, 2007). They contend that the principles of kin selection and inclusive fitness have been overburdened in efforts to explain social behavior in general and eusociality in particular. Instead, they favor an ecological explanation and urge others to consider this approach as well. This approach entails the reintroduction of a version of group-selection reasoning into sociobiology, and a consensus among evolutionary biologists and sociobiologists has not yet developed on this issue.

The Adapted Mind

Supported by the work of anthropologists like Franz Boas and his students Margaret Mead and Ruth Benedict, the notion that the human brain and mind is a general, all-purpose information-processing machine came to dominate sociological thinking by the mid-twentieth century. In terms of information that might prescribe social behavior, the mind was viewed as content-free, until subjected to individual experience or exposed to the influence of culture. This point-of-view eventually became codified into what evolutionary social scientists now describe as the Standard Social Science Model (SSSM) of human nature and behavior. The key elements of the SSSM include the following: (1) Human social behavior is learned, not instinctive. (2) Only by endowing humans with the capacity for culture does the human brain influence social behavior. (3) The kaleidoscopic variability among human societies and cultures constitutes prima facie evidence that the common human genome does not determine human social behavior. (4) Culture, not biology, determines patterns of social behavior and society. (5) The complexity of human social behavior and societies is irreducible to biological factors, such as genes.

The SSSM dominated social scientific thought through most of the twentieth century by promoting oversimplified dualisms such as learning versus instinct, culture versus biology, and social versus psychological determinants of human behavior. The durability of the SSSM in sociological thinking was possible only because many social scientists remained ignorant of a number of key principles regarding biology and social behavior. First, the influence of genes on behavior is not direct. Rather, genes shape behavior indirectly, by guiding the ontogeny of the brain and central nervous system as well as the endocrine system and specifying their functional properties. Second, phenotypes, including social behavior, are not the product of genes alone. Rather, during the process of epigenesis, the environments in which genes reside contribute to the expression of the phenotype that is encoded in the genome. This means that the same genotype can generate a range of phenotypes under variable environmental conditions. The

extent of the range of phenotypes that can so develop is called the norm of reaction. Thus, phenotypic traits, including social behavior, are coproduced by genes and their environments. Third, the SSSM created a false opposition by contributing to the view that behavior must be either learned or instinctive when, in fact, learning itself is understood by evolutionary scientists to be instinctive (Pinker, 1997). The difference between the SSSM view of learning and that of sociobiologists is as follows: the SSSM construes the human brain as a general, all-purpose learning machine, which is equally prepared to learn one thing as well as another. Evolutionary-minded social and behavioral scientists, however, introduce the notion of prepared (or biased) learning, which means that natural selection has installed predispositions to learn and retain some types of information and information contents more readily than others. Specifically, the more adaptively relevant the information, the more likely it can be learned and retained. An example provided by psychologists is the Garcia effect (or Sauce-Béarnaise effect), which refers to ease and speed with which taste aversions can develop in response to potentially toxic foods. The notion of prepared learning has been applied to human social behaviors to suggest that the ability to detect cheating (nonreciprocity) in exchanges relations, identify prospective mates, and detect various forms of threat, for example, may be the product of prepared learning algorithms that evolved by natural selection.

The Phylogeny of Human Sociality

By reconsidering the nature and history of human sociality and societies in light of evolutionary theory, sociobiologists and evolutionary sociologists have begun to call into question long-standing orthodoxy about topics such as the fundamental building-blocks of human society. Specifically, work by Jonathan Turner and Alexandra Maryanski (2008) casts doubt on the assumption that the nuclear family is the primordial social unit from which larger units, including societies, have evolved. By conducting cladistics analyses of primates, especially chimpanzees, Maryanski concluded that humans are not a species that is predisposed to forming strong, durable social ties based on emotional attachments (1992). Instead, she (and later, Turner and Maryanski, 2008) contends that the earliest hominins lived in groups comprising weak social ties, and that social relations were highly ephemeral. This challenges the long-standing assumption that the basic building block of human society was the nuclear family, which was organized on the basis of a very strong pair bond between a male and a female who produced offspring. In fact, the likelihood that the earliest hominins formed social relationships comprising weak ties calls into question the notion commonly held by sociologists that primary groups have always been foundational to the evolution of human societies.

Recent work by Turner and Maryanski revives in new form the old idea that the primordial social units to which humans belong more close resembled a horde, within which social relationships formed and dissolved with considerable ease. By this way of reasoning, it was not until early hominins underwent a transition from an arboreal to a savanna lifestyle that natural selection favored a redesign of the brain that enhanced its emotional capabilities, thereby enabling the formation of strong social ties. The late Miocene Epoch featured a period of climate cooling, which contributed to the decline of forest habitats. As hominin populations were forced to move from forests into open plains and grasslands, they are likely to have confronted new hazards including greater concentrations of predators. The evolution of highly cohesive groups would have been adaptive in such high-risk environments. In response, selection would have favored the enhancement of hominin emotional capacities that could enable the formation and maintenance of strong social ties. While it is well-known that the cortical regions of the human brain are very large and evolved quickly, what is less commonly known is that subcortical regions of the brain are also much larger proportionately in humans than they are among other apes. The subcortical parts of the brain comprise structures such as the diencephalon, the amygdala, the septum, the hippocampus, and the transition cortices. Taken together, they constitute what is sometimes called the limbic systems, and they play a major role in producing and regulating human emotional life. The evolution of the capacity for strong, positive emotions like satisfaction-happiness would support the formation of strong social ties among individuals, and the evolution of negative emotions including shame and guilt would support systems of social control, thereby protecting cooperation from being disrupted by excessive selfishness. Thus, the evolution of an extensive array of emotional capabilities could enable early hominins to be transformed from a weak tie social species whose social relations were easily formed but also easily dissolved, into a strong tie social species with the capacity for forming and maintaining the type of cohesive and durable groups that sociologists call primary groups, including the nuclear family.

In conventional sociobiological thinking, societies are assembled primarily on the basis of common kinship according to the principles of kin selection and inclusive fitness. The population size of kin-based societies can be enlarged by other mechanisms, especially reciprocity among nonkin. In sociobiological theory, common or overlapping genetic interests among individuals provide an incentive for cooperative social interaction, because the fitness benefits of one individual's gains also serve the fitness interests of the other. Among biologically unrelated individuals, cooperation is favored by selection not because individuals share common genetic interests, but rather, because it yields somatic resources (food, protection) from which cooperators can benefit even if they are nonkin. In fact, behavioral biologists have shown that patterns of cooperation can develop even among members of different species, such as the widely discussed relationship between cleaner fish and host fish. Host fish suffer parasite loads that can compromise their health. However, by traveling to cleaning sites in areas such as coral reefs, they can make themselves available to smaller fish that remove the parasites from the bodies of the hosts, thereby gaining food. Though the host fish, a predator itself, could eat the cleaner, it refrains, thereby deriving the benefit of parasite removal by the cleaner. Both participants benefit from this form of cooperation, not because they are kin, but because their behaviors yield mutually rewarding consequences. The host–cleaner fish relationship provides an example of how cooperation can evolve in the absence of close biological kinship.

Trivers's 1971 seminal article on reciprocal altruism converged on a long-standing tradition in sociological thinking that emphasized the importance of reciprocity, exchange, and sharing as the basis of cooperation among groups and societies. Subsequent research on the possibility of reciprocal altruism among both humans and nonhumans elaborated the importance of understanding how social life could evolve on the basis of mechanisms other than kin selection. Much of that research was framed in terms of game theory, and within that tradition, researchers made extensive use of the 'prisoner's dilemma' model of cooperation. The problem of defection (cheating) in the prisoner's dilemma model becomes especially salient from an evolutionary perspective when the parties to cooperation are nonkin. If one individual is cheated by another to whom he/she is closely related, the victim still derives some benefit from the outcome because he/she shares genes with the defector. However, if the defector is a nonrelative, then the victim incurs a net loss in fitness. The importance of outcomes in social interactions comprising reciprocity and exchange has led animal behaviorists to conduct research about the possibility that nonhuman animals might possess capabilities resembling what could be called a sense of fairness. These researchers have adduced evidence among both chimpanzees and New World monkeys that indicates these animals appear to monitor the allocation of resources among members of their groups. This suggests that even some nonhuman primates may possess behavioral mechanisms built into their neuroanatomy for detecting and reacting to cheating.

The highly enhanced cognitive abilities of humans and the importance of reciprocity and exchange in human relationships implies that the ability to detect and react defensively to threats of cheating (nonreciprocity) is even more important in human society than in the social systems of nonhuman species. Experimental research by evolutionary psychologists supports the hypothesis that humans are likely to possess a cheating-detection mechanism that protects them from being victimized in social contracts that involve exchange relations (Cosmides and Tooby, 1992). Subsequent research about the role of emotions in exchange relations has led to the conclusion that emotions such as anger, moral outrage, and a desire for revenge function as a defense against cheating, thereby helping to inhibit the spread of defection within populations of cooperators.

Sociobiology and the derivative discipline of evolutionary psychology hypothesize that the species-typical features of the human brain (and mind) evolved during a time period that began approximately 2.5 million years ago with the appearance of the genus *Homo* and lasted through the hunting-gathering era, the end of which occurred about 10 000 years ago. Current estimates locate the appearance of modern humans about 100 000 to 200 000 years ago. Evolutionary psychologists contend that what they call the cognitive architecture of the human brain is the product of the environment of evolutionary adaptedness (EEA), a configuration of ecological, demographic, and technological environmental factors comprising the selection forces that designed the modern human brain. By this reasoning, the modern human brain and mind represent evolved adaptations to a hunting-gathering social world that is occupied by only a tiny fraction of contemporary humans. The vast majority of living humans reside in and must cope with social worlds that have succeeded the hunting-gathering era, and there is no reason to expect that the human brain is equipped with any specialized, evolved cognitive algorithms for coping with contemporary social environments. This has led scientists to posit a mismatch hypothesis that contends that the evolved properties of the human mind are adapted to a world that has largely vanished, and thus, the adaptability of the human mind may now be more important than the evolved adaptations with which the mind has been equipped by natural selection. The evolutionary sociologist Massey describes this situation by characterizing contemporary humans as strangers living in a strange land (2005).

The transition from hunting-gathering approximately 10 000 years ago to horticultural, agricultural, industrial, and postindustrial eras has provided evolutionary-minded sociologists with opportunities to reflect about familiar topics from a new point-of-view. Specifically, informed by sociobiology, evolutionary psychology, and other evolutionary disciplines, sociologists have posed new questions and posited new explanations of life in contemporary societies. For example, Massey has investigated the possibility that contemporary urban life presents daunting psychological as well as social challenges to its inhabitants (2005). Among such challenges are what can be called diseases of civilization, including mental health problems produced by prolonged exposure to high levels of stress in urban environments. Other health challenges that can be induced by chronic stress include hypertension, obesity, Type II diabetes, Type A personality disorders, immune system deficiencies, memory deficits, and various neurological disorders. Such health problems can intensify social stresses within families, work settings, and other social contexts, leading to social conflict and even violence.

Not all circumstances encountered by a Pleistocene mind living in a space-age world result in dire consequences, however. For example, Massey points to the resiliency with which humans can cope with the scale, anonymity, and impersonality of urban life by organizing themselves into small-scale, intimate social networks that closely approximate the hunter-gatherer band comprising 40–50 or so individuals. Such social networks, sometimes labeled urban villages, have been recognized by urban sociologists for decades and can be understood as manifestations of homophily, a preference to associate with individuals who are similar to oneself, thereby buffering the impersonal effects of large-scale urban environments. Yet, homophilous tendencies that yield closed social networks may also be implicated in the development of closed social networks that constitute social classes and segregated ethnic or racial enclaves, the effects of which can contribute to divisiveness within the larger communities in which they exist. The fate of a small group ape living in a post-EEA social world continues to stimulate research and inquiry by evolutionary sociologists.

Current Inquiry in Evolutionary Sociology

Inspired by sociobiology and related evolutionary sciences, the range of inquiry in which evolutionary sociologists have become engaged is rapidly expanding. The following provides an introduction to the sorts of research endeavors in which evolutionary sociologists are currently engaged. Though not

exhaustive, these areas of inquiry include mating and reproduction, gender and gender inequality, the role of social capital in patterns of social interaction, and dominance relations and patterns of social inequality.

Mating and Reproduction

In diploid species such as humans, males and females derive equal fitness returns from any offspring they produce. However, parental investment is asymmetrical, with females typically incurring greater costs in producing and nurturing offspring. The foundation of this inequality is anisogamy, the difference in size, number, and biological value of gametes. Sperm are small, numerous, and metabolically inexpensive, while eggs are large, few, and metabolically expensive. Furthermore, once fertilized, an egg imposes significant developmental costs on the mother. In a highly altricial (dependent) species like humans, the care and nurturing of offspring imposes much greater parental investment requirements on mothers than on fathers. The most significant form of such investment during the infant's early life is nursing, a cost incurred by females, because males do not lactate (Huber, 2007). A second type of reproductive asymmetry, paternity uncertainty, poses a threat to males but not to females. Barring recent medical developments like the transplantation of fertilized eggs, females are exempt from the experience of maternal uncertainty. However, paternity uncertainty is species-typical for humans, and it has resulted in a wide range of what sociobiologists call mate-guarding strategies developed and deployed by males. Sexual infidelity poses a threat to both males and females, but the nature of the threat and the sexual jealousy that it can activate differs between males and females. Female sexual infidelity threatens males because of paternity uncertainty, while male sexual infidelity threatens females with a potential loss of resources, including paternal investment in offspring. Thus, despite the fundamentally cooperative nature of mating, biological dimensions of reproductive relations also create a foundation for conflicts of interests that are built into human mating systems.

The division of reproductive labor has prompted evolutionary sociologists to look for male–female differences in mate preferences. Rosemary Hopcroft has found that females prefer commitment, social status, and resources in mates, while males cue on indicators of fertility, such as youth and beauty, and to a lesser extent than females, resources as well (2009). Furthermore, there is a stronger correlation between social status and fertility for men than for women. In an empirical test, Hopcroft reported results that were consistent with the Trivers–Willard hypothesis, which states that parental status influences differential parental investment in sons and daughters. Specifically, she found that boys in high-status families attain more years of formal education than do girls, but in low-status families, girls receive more support and attain more years of education than do boys. Sociobiologists explain such patterns in terms of differences between male and female lifetime potential fitness, with male potential fitness far exceeding that of females.

Gender and Gender Inequality

As discussed previously, an evolutionary sociologist has proposed that female lactation in humans imposes opportunity costs on mothers that are not incurred by males (Huber, 2007). In traditional societies, the birth of each child requires intensive maternal investment until the child is at least 4 years old. If the female bears several children in succession, this can deprive her of participation in areas of public life such as economics, politics, and military service, all of which provide males with status-attainment opportunities. Huber attributes the evolution of patriarchy among humans to this aspect of the reproductive division of labor in humans. Not until infant formula was developed was this aspect of maternal investment relaxed, making possible the development of more egalitarian relations in parenting.

Even before the emergence of sociological inquiry that is informed by sociobiological theory and research, social scientists had documented the influence of sex ratios on patterns of gender inequality (Guttentag and Secord, 1983). Specifically, high sex ratios create a scarcity of potential mates for males, thereby maximizing female dyadic power in choosing mates. Males commonly react to this power disadvantage by trying to limit female discretion in mate-selection interactions. In evolutionary terms, males try to restrict female choice and minimize male–male competition, both of which are important components of sexual selection. Restated in sociobiological terms, the Guttentag–Secord theory of sex ratios predicts that high sex ratios will activate male sexual jealously and maximize efforts by males at mate-guarding. Thus, demographic properties of a society can activate evolved psychological propensities for behaviors that represent efforts to respond adaptively to conflicts of interest.

Hopcroft attributes the roots of gender inequality and sex discrimination to evolved differences between male and female psychology (2009a,b, 2005, 2002). Like Huber, she uses evolutionary thinking to try to identify the phylogenetic origins of gender inequality in general, and patriarchy in particular. Unlike Huber, she explores the possibility of the existence of male–female differences in evolved psychology that could be implicated in the origins, development, and maintenance of patterns of gender inequality. Specifically, Hopcroft documents a pattern whereby adolescent girls tend to defer to males, but males of similar age do not defer to females. Conversely, adolescent females do not defer to other adolescent females. Hopcroft explains that young men should find deferential females more attractive as potential mates, because they pose less of a threat of paternity uncertainty and less of a challenge to mate-guarding efforts. Hopcroft notes that females from the ages of 15–18 typically experience lower self-esteem than do males of the same age, despite being more academically successful and less-likely to manifest behavioral problems. She interprets this anomaly using sexual selection theory, and speculates that the pattern of lower self-esteem among females in this age range may be an expression of evolved female deference to males. In her view, deferential female behavior to a male who is a prospective mate signals the promise of fidelity, thereby relieving males of the anxiety of paternity uncertainty in a future reproductive partner.

Hopcroft considers the alternative possibility that deference in young females toward males may be the product of culture and socialization alone. If so, she predicts that female deference to males should persist through all stages of the life

cycle, since the effects of patriarchal culture are not relaxed as women age. However, Hopcroft reports that female deference to males declines as women enter postchildbirth years, and the status of women in all societies rises as women pass menopause.

Social Capital

Social capital theory contends that social relationships are resources that can lead to the development and accumulation of human capital. For example, a stable family environment can support educational attainment and support the development of highly valued and rewarded skills and credentials. In evolutionary terms, social capital can be defined as any feature of a social relationship that yields reproductive benefits. According to Savage and Kanazawa (2002, 2004), humans have evolved preferences for companionship in general, and specific preferences for cues that signal higher levels of social capital. Since evolved preferences for certain types of social relationships should have been selected in the EEA, we can expect to observe gender differences that reflect the division of labor in foraging societies. For example, females can be expected to value and derive emotional satisfaction from membership in small social networks comprising close personal relationships constructed from strong social ties. These types of relationships would be especially adaptive for women by providing assistance in foraging and caring for children. Males would be expected to benefit more from membership in larger social networks constructed from weak ties that would constitute hunting groups, political alliances, and fighting parties. Males would benefit especially from forms of social capital that would confer resources and social status.

Savage and Kanazawa (2002) contend that reformulating sociological explanations of crime in terms of evolutionary theory can provide new insights about deterrents to crime. Specifically, choice and social control theories, cultural deviance theories, and strain theories all suggest that the threat of losing social bonds can be a powerful inhibitor of deviant or criminal behavior. Evolutionary theory invites predictions that social ties and relationships that were most closely related to reproductive success in the EEA are especially likely to produce a deterrent effect against deviance and crime. For women, behavior that would jeopardize close personal relationships would be particularly costly, thus, the threat of losing those relationships would deter such behavior. For men, social capital that yields material resources and social status is especially valuable, and the threat of losing those resources would be likely to inhibit deviant or criminal behavior. This type of reasoning is consistent with empirical findings that document male sensitivity to status loss or degradation.

Dominance and Social Inequality

Both sociologists and evolutionary behavioral scientists, including sociobiologists, study dominance relations and social inequality. Evolutionary sociologists look for the phylogenetic origins of social inequality in the evolved psychology of humans as well as the ecological contexts in which humans evolved and now live. Dominance hierarchies are established in face-to-face interactions among individuals and determine access to resources, including both reproductive resources (mates) and somatic resources (food, territory, and other material resources). In addition to dominance hierarchies, both official hierarchies (position rankings in formal organizations) and socioeconomic hierarchies (e.g., social class systems) exist in human societies. Evolutionary thinking has had more influence on the study of human dominance hierarchies than on official or socioeconomic hierarchies, though recently it has begun to be integrated into the study of phenomena such as class relations in urban areas (Massey, 2005).

Work by evolutionary sociologists like Mazur (2006, 2005) and Booth et al. (2006) has established a link between testosterone and rank in dominance hierarchies, but not aggression. In fact, Booth et al. (2006) have determined that the effect of testosterone on behavior is mediated by social relationships like parent–child relations, peer relations, and relations to siblings. Mazur (2006) has also determined that testosterone levels in males both influence and are influenced by dominance contests and their outcomes. Mazur also documented a relationship between testosterone levels and honor cultures which, in turn, influences levels of violence among young men.

Among nonhuman species, status (social rank) is positively correlated with reproductive success, but among humans, the correlation is equivocal (Hopcroft, 2006). In fact, some studies have found a negative relationship between social status and reproductive success. However, evidence suggests that the relationship differs between men and women, and that for men, higher social status is associated with fathering more children. Another area of research pertaining to evolution and social inequality is illustrated by the Trivers–Willard hypothesis, the prediction that wealthier families will invest more resources in support of sons, but poorer families invest more in support of daughters. While Freese and Powell (1999) failed to adduce evidence in support of Trivers–Willard, Kanazawa retested the hypothesis using sex-neutral measures and reported findings that indicate weak support for the hypothesis.

Finally, in reflecting on the implications of humans exhibiting an evolved psychology that is incongruous with the social and demographic characteristics of contemporary, urban-industrial societies, Massey (2005) discusses the possibility that an evolved propensity for homophily may help explain the development of social networks that constitute both ethnic enclaves and urban villages in large metropolitan areas. Evolutionary processes such as kin selection and reciprocal altruism may underpin the development of such networks. And though such networks can provide support for their members, they also can reinforce stratification systems by isolating groups of people from each other, creating both networks of privilege and networks of poverty. Massey further explains that because processes like kin selection and reciprocal altruism promote mutual assistance among, but not between, members of these networks, networks of poverty are often depleted of the resources they share among themselves, while cooperation among members of networks of privilege increase the resources that are available to members of those networks. Thus, an evolved psychology

designed for cooperation and sharing among members of societies in the EEA can, ironically, impose significant burdens on members of social networks comprising lower class positions in society.

Abstract

The last third of the twentieth century saw a change in evolutionary reasoning from group selection to kin selection and from a focus on the individual to a focus on its genes instead. The theoretical breakthrough came with William D. Hamilton's 'inclusive fitness.' Although Edward O. Wilson's *Sociobiology: the New Synthesis* and Richard Dawkins' *The Selfish Gene* provided important scaffolding, the emergence of the actual research paradigm can be described as a collective process of mutual influences and distributed leadership. As research in 'sociobiology' under different names continued to expand and flourish, the first decade of the twenty-first century saw a challenge to the reigning paradigm, stimulating the further proliferation of research topics as well as integration of the field.

The Rise of the Sociobiological Paradigm

What's in a Name?

'Sociobiology' emerged as a new integrative discipline during the second part of the twentieth century. It transformed the study of animal social behavior into a field based on Neo-Darwinian reasoning, which interprets evolution as a change in gene frequencies in populations. This made it possible to develop mathematical models that could be subjected to empirical testing, turning traditional natural history into a more rigorous science.

The name 'sociobiology,' however, did not become the name in use for practicing biologists. Many scientists involved in what would have been counted as bona fide sociobiological research actively avoided the term, instead calling themselves as behavioral ecologists or functional ethologists. This was largely because of the political connotations of sociobiology caused by the debate around Harvard zoologist Edward O. Wilson's (1975) book *Sociobiology: The New Synthesis*. Those involved in what might have been called 'human sociobiology' were particularly sensitive, preferring to be called biosocial anthropologists, human ethologists, human behavioral ecologists, or Darwinian anthropologists. From the 1990s onward, much sociobiological research went under the new label 'evolutionary psychology.'

As it turned out, Wilson's particular, broadly conceived sociobiological research program identified in his book did not become the approach that was in fact used by practicing 'sociobiologists' (although they did not call themselves that). Instead, the actual sociobiological research paradigm-in-use consisted of a quite small but connected collection of theoretical insights introduced by Richard Dawkins' *The Selfish Gene*.

A Paradigm Shift

By the early 1970s a significant amount of both new theory and empirical studies of animal social behavior using an evolutionary perspective had accumulated. Social behavior was now regarded as undergoing evolution – just as morphological traits did – and treated in a quantitative way that allowed for predictions to be made. The excitement was so palpable that it caused some scientists to feel that they had experienced a personal 'paradigm shift.' For others again, the extension of an evolutionary perspective to human social behavior was both politically dangerous and scientifically unsound; it was 'bad science' that needed to be sharply criticized.

The core idea that revolutionized thinking was William Hamilton's concept of inclusive fitness, or alternatively, 'kin selection.' This central insight was followed by Robert Trivers' important papers on reciprocal altruism, parental investment, and parent – offspring conflict, and John Maynard Smith's concept of Evolutionarily Stable Strategy. The person who most strongly advocated for a change away from group selection was George Williams. His famous 'canon' effectively ruled out vague references to 'the good of the species' that could be found in textbooks of the time. Williams argued firmly that when formulating adaptive explanations, one should not involve higher levels of organization than absolutely necessary. Unless there existed compelling evidence to the contrary, one should stick with the simplest form of natural selection: that of alternative alleles in Mendelian populations.

What united the new theoretical approaches was a game-theoretical perspective, whereby genes could be imagined as strategic agents causing their carriers to behave in their (the genes') own interest, that is, to get propagated. Hamilton sometimes used this imagery in his papers, but it was Dawkins who took it to new heights in his popular book.

A Collective Effort

Many have noted a surge of books and articles published in the mid-1970s, summarizing and discussing the new ideas. Among these various 'syntheses' were textbooks by Jerram Brown and John Alcock, and Robin Fox' *Biosocial Anthropology* (based on a 1973 Oxford conference covering issues in human sociobiology) all published in 1975. Among seminal articles were Richard Alexander's long 1974 contribution 'The Evolution of Social Behavior' in *Annual Review of Ecology and Systematics*, and shorter articles by Alexander (1975), West-Eberhard (1975), and Maynard Smith (1976). Together, this makes for quite a concentration of intellectual, synthetic effort in the mid-1970s. What got particularly emphasized, however, were Wilson's *Sociobiology* and Dawkins' *The Selfish Gene*.

These two books became central for the early scaffolding of the emerging sociobiological paradigm. They were written independently of each other and were in fact quite different. Still, in a strange complementary way, Wilson and Dawkins together were able to claim the new field and identify its intellectual content. Wilson surveyed the territory, gave it a name, and handed it over to his animal behavior colleagues. Dawkins explicated the underlying logic of the field and identified the core theories.

At the same time there was an unusual amount of personal interaction and mutual reinforcement taking place, also across the Atlantic. Hamilton was influenced by the American, George Price, who had come to live in England. Price also collaborated with Maynard Smith. Young Hamilton was early on encouraged particularly by George Williams, finding in him a kindred soul. E.O. Wilson was an early supporter of Hamilton and a later supporter of Trivers, a doctoral student at Harvard, who worked closely with anthropologist Irven De Vore, who had been deeply inspired by Hamilton. Trivers' early papers, which extended a Hamiltonian type of reasoning, were an important inspiration for Dawkins (1989, p. 298). Dawkins asked Trivers to write the Preface to his book; Hamilton encouraged Trivers. Dawkins' and Wilson's books served as vehicles for spreading Hamilton's and Trivers' ideas, and Dawkins' book for the ideas of Williams, Maynard Smith, and so on.

There also was an important irritant – a book that many regarded as 'wrong': Vero Wynne-Edwards' (1962) group selectionist explanation that the mass gatherings and displays of grouse were means for population regulation and altruism for the good of the species. Williams and Maynard Smith were among those who felt challenged to prove him wrong.

One particular conference may well have been a crucial factor in the development of sociobiology, the lavish "Man and Beast" conference arranged at the Smithsonian Institute in Washington, DC, in May 1969. Entitled "Comparative Social Behavior," it gathered an abundance of eminent academics from the United States and elsewhere – largely biologists, including anthropologists and philosophers interested in evolutionary questions. Konrad Lorenz' (1966) book *On Aggression*, and popular ethological books championing a fundamentally brutish human nature had made biologists seem like relevant consultants on the problem of social violence, examples of which had been recently experienced in the US.

Among the invited were Edward Wilson, Richard Alexander, and young William Hamilton, as well as biosocial anthropologists Lionel Tiger and Robin Fox, Napoleon Chagnon, and William Irons. For Wilson, the conference was 'an early milestone in the development of sociobiology.' The conference and the resulting edited volume reinforced his belief that a common language was possible. 'The ingredients for Wilson's *Sociobiology* were all there!" as one of the organizers later noted.

Wilson's book had an ambivalent approach to ethology. At the beginning of his book he provocatively declared that ethology was going to be swallowed up by sociobiology by year 2000. Others commented that much of *Sociobiology* itself could as well have been found in a traditional ethology book (e.g., Crook, 1976). *Sociobiology* may in fact have stolen the show from similar summarizing efforts in ethology at the time, for example, Bateson and Hinde's *Growing Points in Ethology* (1976).

Such views illustrate the confusion about the actual meaning of 'sociobiology' at the time. Was it the name to be identified with Wilson's broad definition, the study of social behavior of all animals, or the more specific quantitative approach he had also recommended in his book – involving various population parameters and drivers of evolution – or with a set of particular new ideas of a handful of individuals?

From Group Selection to Kin Selection

Inclusive Fitness and Kin Selection – a Closer Look

If the shift from individual selection to group selection after World War II had been a 'stampede' (Hamilton's expression), then between the mid-1960s and mid-1970s we had yet another 'stampede,' this time from group selection to kin selection. According to some observers, if around 1965 you had to be a group selectionist to get published, 10 years later you had difficulty getting published if you were not a kin selectionist. As mentioned, some biologists experienced this paradigm shift as an intense personal revelation. In some departments, tensions arose between group selectionists and newly "converted" kin selectionists. Personal relationships were affected. 'Stampede' also meant that many rushed into kin selection without bothering to read Hamilton's (1964) paper very closely, or at all (see, e.g., Grafen, 1982).

The scientific breakthrough in sociobiology had come with Hamilton's mathematical demonstration of the conditions under which it would be possible for altruism as a genetic trait to evolve. (Altruism was here defined strictly as behavior that benefits the recipient, while incurring a cost for the donor.) 'Hamilton's rule' (Hamilton, 1963) postulates that altruism can evolve if the reduction in fitness (number of offspring) of the donor is more than made up for by the increased fitness (number of offspring) of the recipient. It is simply expressed in the formula $k > 1/r$, where k is the cost – benefit ratio of the behavior and r is the coefficient of relatedness between two individuals.

Hamilton developed his theoretical argument in more detail mathematically in a long two-part paper in the *Journal of Theoretical Biology 1964* (this became part of his PhD thesis which consisted of his first four published articles on aspects of social behavior). His basic ambition was to improve on R.A. Fisher's 'Fundamental Theorem of Natural Selection,' which mathematically expressed evolution as a change of gene frequencies in populations. Fisher in his path-breaking 1918 paper had shown how evolution could be interpreted mathematically – it could be regarded as the work of natural selection on the existing genetic variability in a population (assumed to be generated by constantly emerging small mutations). This is why Fisher equated fitness with the availability of such variation, that is, the statistical 'variance.'

Hamilton, a great admirer of Fisher, while always striving for the most general principle, realized that he could make Fisher's theorem even more fundamental by including the fact that individuals typically live in social groups and affect one another's life chances (especially number of offspring). The concept he coined was 'inclusive fitness.' Inclusive fitness added to Fisher's 'classical' individual fitness an additional component to express the effect of the individual on the fitnesses of its

relatives, as well as their effect on the individual's fitness (the effects could be both positive and negative).

Hamilton struggled a lot with the derivation of this formula and its mathematical formulation, and the paper is often said to be hard to read. It was also almost immediately misunderstood. What was missed, especially, was that 'individuals' here could be any types of organisms, for instance plants (which Hamilton discussed in the paper), and that individuals could share genes without being proper relatives – they could for instance identify each other by some similar phenotypic trait, or even preferences for similar habitats. Hamilton called this a 'superkinship' trait; Richard Dawkins in *The Selfish Gene* later suggested calling it a 'greenbeard trait.' (We see here an implicit recognition of the theoretical possibility of some kind of group selection.)

The paper that launched inclusive fitness was called "The Genetical Evolution of Social Behavior." It discussed in fact four types of social behavior: selfishness, cooperation, altruism, and spite. These could be organized in a 2 by 2 matrix as to the gain and loss to two interacting individuals: A gains, B loses; both gain; A loses, B gains; and both lose. (In 1970, Hamilton modeled spite in a new, useful way with the help of the Price equation, opening up a new field of research.)

Scientists soon started using Hamilton's rule as a convenient shortcut. This opened up a burgeoning new scientific research enterprise of testable models of animal social behavior. Likewise, 'kin selection' soon became the way in which inclusive fitness was understood in practice, that is, as natural selection acting on a group of relatives.

Hamilton and Maynard Smith

It was Maynard Smith (1964) who introduced the term 'kin selection' as an alternative to 'group selection' (a process of natural selection among groups rather than individuals, the idea being that a group of altruistic individuals would have an advantage over other groups; they did not need to be related, just possess the altruistic trait). Maynard Smith (like others, such as George Williams) believed group selection to be an unlikely phenomenon in nature, because even if groups with many altruists would have a clear advantage, the problem was to achieve the initial spread of altruism in a group of selfish individuals. How would individuals with altruistic genes ever be able to proliferate in a group before getting 'outreproduced' by selfish group members?

Hamilton never got over his belief that Maynard Smith, by launching the notion of kin selection, had tried to usurp his (Hamilton's) priority for the solution of the altruism problem. (Hamilton had realized that for altruism to evolve, the benefit of altruistic acts would need to fall on individuals likely to share genes with a donor. For relatives, this likelihood of shared genes, or 'coefficient of relatedness,' is ½ for parent – offspring and for siblings, and 1/8 for first cousins.) As he was struggling with the revision of his long 1964 paper for the *Journal of Theoretical Biology*, Maynard Smith had introduced the term 'kin selection' in a short piece in the highly prestigious scientific journal *Nature*. Also Maynard Smith's oft-repeated reference to J.B.S. Haldane as having 'said it first' triggered recurring bouts of suspicion in Hamilton. Haldane had allegedly said in a pub quip that he would lay down his life for (more than) two brothers or eight first cousins. (For a discussion of the Hamilton – Maynard Smith relationship, including a revealing letter exchange, see Segerstrale, 2013.)

It was Maynard Smith who had been the referee for Hamilton's long manuscript, and had asked for major revisions, which delayed publication. Maynard Smith, however, insisted that his suggestion to split it in two (with 'inclusive fitness' introducing part two) and to provide naturalist examples in fact saved the paper's readability. Also, according to Maynard Smith, the term 'kin selection' was born in a meeting with himself, David Lack, and Arthur Cain as they were together looking for an alternative to Wynne – Edwards' group selection approach.

There was a serious scientific problem as well. The term 'kin selection' did not capture the true, universal meaning of inclusive fitness (see below). It also misrepresented the relationship between kin selection and group selection. Hamilton himself did not see these two as opposed to each other, or kin selection as an alternative to group selection. This was already implicit in his 1964 paper, as seen above, and became clearer in 1970 and 1975 when he re-derived his original inclusive fitness formula from group selectionist premises with the help of the Price equation (which makes it possible to assess the total distribution of genetic variance inside and outside groups in a population).

Hamilton wanted 'inclusive fitness' to be a universal concept – broader than 'kin' selection, 'group selection,' or even 'reciprocal altruism.' He reasoned that many possibilities in fact existed: altruists may live with altruists simply because they have never parted, or because they are able to recognize fellow altruists (later Dawkins' 'greenbeard effect') or due to some pleiotropic effect of the altruistic gene on habitat preference. Therefore, the appropriate choice of terminology – kin selection, group selection, kin-group selection, low migration, assortation, etc. – would depend on the nature of the case in question (Hamilton, 1975).

Hamilton himself, however, did surprisingly little to publicize his later and "more elegant" Price-inspired inclusive fitness model, or even actively correct misunderstandings (others who did so were Dawkins, 1979 and Grafen, 1982; for Hamilton's motives see Segerstrale, 2013).

The Sociobiology Controversy – a Polarizing Episode

The Early Attacks

Wilson had defined sociobiology as 'the systematic study of the biological basis of all social behavior.' The idea was that, just like other features, behavior, too, was undergoing evolution. His book was intended as an encyclopedia of all the new information about animal social behavior, both theories and empirical studies that had accumulated over several decades. In this endeavor Wilson saw himself as continuing the work of the neo-Darwinian or Modern Synthesis – the grand fusion of Mendelism and Darwinism, and its extension to a number of biological fields (e.g., systematics, paleontology, and botany) – by incorporating also the field of behavior.

In his last chapter Wilson argued that a number of human behaviors, including sex roles, aggression, altruism, and even moral and religious beliefs could well have a biological basis.

To boost this argument, he drew parallels to the behavior of other primates and invoked existing research on selected traits from human behavioral genetics and twin studies. For a group of academics radicalized in the 1960s, however, Wilson's statements clearly supported a biological determinist view of humans, suggesting that social inequality was 'in our genes,' which would make social reforms futile.

The announcement of Wilson's book as news on the front page of *New York Times* in May 1975 triggered the spontaneous formation of the Sociobiology Study Group, among which could be found two of Wilson's Harvard colleagues, Richard Lewontin and Stephen J. Gould. The criticism of sociobiology soon escalated from a condemnatory letter in the *New York Review of Books* signed by Boston area academics to the famous incident at the 1978 meeting of the American Association for the Advancement of Science in Washington, DC, where some activists from the Committee Against Racism, rushing up from the audience to Wilson on the podium, poured a pitcher of ice-water in his neck.

The year 1975 was a time of liberal academic outlook and a lingering postwar taboo on biological explanations of human behavior. This was also the time of postwar 'culturism' promoted by people like Margaret Mead in anthropology and the behaviorist B.F. Skinner in psychology. But Wilson had violated the taboo and dared discuss biological underpinnings for human behaviors. The critics decided to forcefully denounce him as a 'bad' scientist, both morally and scientifically.

According to the Sociobiology Study Group, Wilson's real aim was to promote a conservative political agenda by defending social inequality as a natural state of affairs.

Wilson, dismissing his critics as 'tabula rasa Marxists,' steadfastly denied that he was considering these kinds of political consequences; rather, his primary goal was to provoke the social sciences into taking biology seriously. (It is true, though, that Wilson regarded himself as a taboo breaker and took pride in it.) Many may have quietly sided with the critics or been intimidated by the upheaval – very few of Wilson's colleagues came to his defense. The cultural and political climate was not on his side.

The critics' condemnation even extended to the name 'sociobiology.' Wilson himself explained that the logic of this kind of discipline had been apparent much earlier, and that he was simply following in the footsteps of J.P. Scott who had used this name within the Animal Behavior Society for a field located between biology and psychology and sociology (Wilson, 1980). For many political critics, though, the association was directly to 'social biology,' which in turn brought the thinking to 'Sozialbiologie' and its Nazi connections (e.g., Chorover, 1979). And after the scandal around Wilson's book, regular scientists, too, avoided calling themselves sociobiologists lest they be seen as accepting the field's alleged political goals. However, Patrick Bateson at King's College, Cambridge, who wanted a name for functional studies of social behavior that were not necessarily ecological, found the name 'sociobiology' handy. After much discussion with the participants in his new research seminar on sociobiology, and considering the political criticism, the resulting book bravely appeared as written by the King's College's Sociobiology Group and entitled *Current Problems in Sociobiology*. Others again resisted the label 'sociobiologist' because they felt that Wilson's view which embraced group selection, clashed with their own newly acquired gene selectionist view.

The Political Critique of 'Bad Science'

The big political concern of the critics (largely 1960s academic radicals) was that any biological explanation would automatically legitimize the social status quo and discourage social reform. This belief went hand in hand with the assumption that ideologically influenced bad science inevitably leads to bad social consequences. What to do? The critics simply appointed themselves 'weeders' of anything that seemed like bad science. What then was bad science? Anything involving modeling of hypothetical genes and other indirect approaches rather than experimental science – such fields as behavioral genetics, IQ research, and sociobiology (not surprisingly, many leading critics came from experimental fields). A critical industry was born, all set on revealing the underlying ideology of political conservatism, racism, sexism, and so on of 'bad science.' Meanwhile, those who defended sociobiology, behavioral genetics, and similar fields trusted the traditional 'linear' model of scientists producing useful results, which society later decided on in its democratic process (see Segerstrale, 2000a).

In relation to both *Sociobiology* and *The Selfish Gene*, the critics employed a particular reading strategy which I have called 'moral reading.' The aim was to imagine the worst possible social or moral consequences of selected sentences in the book, which were then held up to show the author's nefarious intent. Both Wilson's sometimes speculative language and Dawkins' colorful imagery of genetic strategies were clearly gold mines for the critical industry. Dawkins' particular nemesis was the British neurobiologist Steven Rose.

This move effectively served to obscure the profound difference between the Wilsonian and Dawkinsian approaches. Wilson's sociobiology was of a systemic, integrative kind. He was interested in bringing all social behavior under one big comparative umbrella, making sociobiology a comprehensive quantitative and predictive science. Dawkins, in contrast, wanted to explain to his readers a new way of thinking about evolution. Moreover, in his book, Dawkins was not including the human species. In fact, he relegated humans to the realm of culture – dominated by memes – transmittable information packages. This was largely ignored by the critics.

Centers for Education and Research

As the sociobiology controversy was raging, serious research and education was going on in a number of places. One of the most active leaders in the emerging field of sociobiology – although he did not call the field that – was Richard Alexander at the University of Michigan. Originally a specialist on crickets, his later claim to fame was to predict the existence and behavior of the first sociobiologically behaving mammal – the naked mole rat – before it was actually found. Alexander had retrained himself and also became a practicing human sociobiologist (or rather Darwinian anthropologist). Under his leadership Ann Arbor became an El Dorado for American graduate students of evolution, especially as he regularly invited important figures, such as John Maynard Smith, William Hamilton, or George Williams, to visit for a semester.

Hamilton arrived in 1977, and in 1978 Alexander together with Donald Tinkle was able to arrange a position of Museum professor for him. The many brilliant students from Hamilton's seminars later became eminent professors in the United States.

Meanwhile, George Williams ran an equally dynamic department at SUNY, Stony Brook, for a quarter century after his arrival in 1966, the year of publication of *Adaptation and Natural Selection*. Williams, an ichthyologist, gathered a large number of graduate students around him. Just like Hamilton, he was interested in basic principles, looking especially for seeming exceptions. Both Hamilton and Williams recognized that they were twin brothers of sorts, both in regard to their scientific taste and choice of topics (such as senescence, mate choice, and the evolution of sex), and even in personality features, despite their 10-year age difference. Williams was also the influential editor of the *Quarterly Journal of Biology* during the latter part of the twentieth century.

John Maynard Smith, meanwhile, had become the new Dean of Biology at the University of Sussex in 1965. Originally as an engineer and a student of JBS Haldane, he was a keen follower of biological developments and a great clarifier of issues, with a knack for coining useful concepts (such as kin selection and Evolutionarily Stable Strategy). He typically published lucid short articles on new ideas. As he once admitted, he did not always know where he got his ideas from – indeed, he processed a great amount of material, especially as a reviewer for the *Journal of Theoretical Biology*, *Nature*, and other journals. His collaborations with students and colleagues resulted in a large number of articles. His fair-mindedness gave him an unusual position in the sociobiology debate: although he sympathized with the political views of Lewontin and Gould, he refused to go along with their attack on gene-selectionist reasoning.

Other centers of activity were Oxford and Cambridge. At Oxford Richard Dawkins, John Krebs and others were busy from the early 1970s with various sociobiological game-theoretical scenarios, such as arms races. (However, they did not call the field sociobiology, but rather called it 'behavioral ecology' or 'functional ethology'.) In 1984 they were joined by Hamilton, who had left Ann Arbor to become a Royal Society Research professor at Oxford. By now, Hamilton had moved on to a different topic, the question of sexual reproduction and the role of parasites (pathogens) for its evolution and maintenance. Hamilton had a small number of graduate students of his own (he had no teaching duty), but was typically the informal adviser of visiting postdocs.

At Cambridge, Patrick Bateson, an integrating force, led an empirically oriented multiyear Sociobiology seminar of invited speakers, the King's College's Sociobiology Group, who together produced *Current Problems in Sociobiology*.

Coping with Culture

Sociobiology and Anthropology

In the last chapter of *Sociobiology* Wilson admitted that, compared with culture, evolution by natural selection in general was slow, and also that the genetic differences *between* different human populations were indeed small compared to the genetic variation *within* each population (here, he agreed with those who doubted the usefulness of 'race' as a biological category). Still, in a statement that alarmed his critics, he argued that the genes "maintain a certain amount of influence at least in the behavioral qualities that underlie variations between cultures" and that "even a small portion of this variance may predispose societies toward cultural differences." As examples he mentioned heritable psychological traits such as introversion and extroversion, or dominance and depression. More boldly, he suggested that potential "multiplier effects" might be able to speed up human evolution. What was needed, he suggested, was a new anthropological genetics (1975, pp. 550, 569–570).

Wilson discussed this idea in a short chapter in *Human Social Behavior: An Anthropological Perspective*, edited in 1979 by anthropologists Napoleon Chagnon and William Irons, then at Northwestern University. Biosocial anthropologists, as they called themselves, early on thought along sociobiological lines and there was cross-pollination of sorts. For instance, in *Sociobiology* Wilson quoted Lionel Tiger's idea of a human 'biogrammar.' Another biosocial anthropologist was Robin Fox, the convener of the 1973 Oxford conference on 'biosocial anthropology' and editor of the book with the same name. (Hamilton noted that had this conference been held 2 years later, it would have been classified as human sociobiology.) Fox and Tiger, alone or together, contributed a number of popular books in this broad biosocial or sociobiological spirit, such as *Men in Groups* and *The Imperial Animal*.

More work in the same spirit was pursued by the group at the University of Michigan, who called themselves 'Darwinian anthropologists,' which meant they applied kin-selectionist and other sociobiological models directly to such things as marriage arrangements, patterns of inheritance, or child abuse. Together some of these biosocial and Darwinian anthropologists, including Chagnon and Irons, and the evolutionary psychiatrist Randy Nesse, later took the initiative to the Human Behavior and Evolution Society, founded in 1988, with Hamilton as its first president.

Sociobiology Transforms Itself – or Does It?

While the Chagnon and Irons book contained Wilson's short piece arguing for a genetic anthropology, it also sported the more complex coevolutionary theory of anthropologist William Durham. It is not necessary to presume genetic predispositions for all adaptive behaviors, he argued. Humans might be maximizing their inclusive fitness for both cultural and biological reasons. A type of cultural selection may sometimes even replace natural selection: people may maintain a behavior which is no longer adaptive because of its continuing cultural association with high status.

In the early 1980s, Wilson decided to reconsider the relationship between genes and culture. In *Genes, Mind, and Culture* (1981) produced with Charles Lumsden, a young theoretical physicist, he demonstrated how the human mind, influenced by genes, tended to choose survival-promoting cultural elements. Here he could now respond to those who had criticized sociobiology for not addressing cultural differences. Wilson saw *Genes, Mind, and Culture* as a new version of sociobiology. Still, his and Lumsden's particular coevolutionary process was clearly aimed at 'keeping culture on a leash.' This

was achievable through 'the epigenetic rules' which connected genes with culture by affecting individuals' choices of cultural behaviors or artifacts, seen as isolated units ('culturgens') that could either be chosen or discarded. In *Promethean Fire* (1983), the authors discussed the gene – culture coevolution in a popular form.

Robert Boyd and Peter Richerson at this time (1985) worked with 'dual inheritance' models, which considered biological and cultural evolution at the same time, while Cavalli-Sforza and Feldman (1981) constructed Darwinian models of cultural evolution. These models afforded much greater opportunity for culture to affect genetic evolution and drive behavior to novel equilibria, departing from Lumsden's and Wilson's assumption that genes keep culture on a tight leash.

The idea of a coevolutionary feedback loop that included the mind stimulated other research at the time (while the particular mathematical models from *Genes, Mind, and Culture* were not used). Later, looking back, however, Wilson was disappointed with the lack of progress in the field of gene – culture coevolution, a field where the processes quickly became intractable and the models too complex. But there was also serious criticism. Social scientists strongly disagreed with the depiction of culture as a "sum of mental constructs and behaviors, including the construction and employment of artifacts" (e.g., Leach, 1981, p. 3). Maynard Smith and Warren (1982) questioned the mathematics.

Evolutionary Psychology – the Same or Different?

As Wilson in the 1980s moved away from sociobiology toward environmental activism (Wilson, 1984, 1992), an opportunity opened up for the emerging field of evolutionary psychology. This field was energetically promoted by Harvard-trained anthropologist John Tooby and psychologist Leda Cosmides, who were in turn supported by Harvard's Irven De Vore and other biosocially oriented anthropologists. Donald Symons in turn brought Tooby and Cosmides to Santa Barbara and helped found the Center for Research in Evolutionary Psychology.

Evolutionary psychology tried to actively distance itself from sociobiology and its political connotations. It was not dealing with genes but with universal features of the human mind, which was presented as once and for all formed in the Environment of Evolutionary Adaptedness (EEA). Evolutionary psychology also declared itself uninterested in such things as IQ and behavioral genetics. The mind is seen as a Swiss army knife, composed of a set of modules for solving typical problems encountered in the EEA and culture is based on a combination and extension of these. The 'bible' of this field, *The Adapted Mind* was published in 1992, with Tooby and Cosmides bringing in the established biosocial anthropologist, Jerome Barkow as a coeditor. Just as sociobiology had made the cover of *Time* magazine (1 August 1977), it was evolutionary psychology's turn to do the same (28 August 1995). It was also covered in popular books such as David Buss' *The Evolution of Desire* (1994) and Robert Wright's *The Moral Animal* (1994).

Evolutionary biology may well have seemed as an alternative paradigm to sociobiology. However, Wilson from the very beginning insisted that evolutionary psychology was the same as human sociobiology (Wilson, 1998). At the inaugural meeting of the Human Behavior and Evolution Society in Evanston, 1989, Wilson wondered why it did not call itself the Society for Human Sociobiology instead – the obvious name, according to him.

That was a meeting attended by all the leading names in 'sociobiology' – William Hamilton, E.O. Wilson, George Williams, Richard Alexander, Richard Dawkins, and Irenaeus Eibl-Eibesfeldt. What Wilson meant when he said that evolutionary psychology was 'the same' as sociobiology was most likely his revised view in *Genes, Mind, and Culture* where the epigenetic rules figure prominently. And indeed, the epigenetic rules were described as rules that guided the development of mind.

However, sociobiology is not typically seen as a science of the mind, and the name had already been saddled with political connotations. In 1996 a news notice reported that the Human Behavior and Evolution Society's journal was changing name from *Ethology and Sociobiology* to *Evolution and Human Behavior*. The report produced a protest from a number of HBES members who regarded themselves as practicing sociobiologists (Hrdy et al., 1996).

The Sociobiology Controversy Turns Scientific

Realism versus Adaptationism

As Wilson moved on to gene – culture coevolution, and later on to biodiversity and the environment, it was largely Dawkins who took up Wilson's mantle. In the early 1980s it was rather he and Gould who emerged as the most visible sparring partners in the sociobiology controversy. Meanwhile the controversy also moved away from strictly political issues and toward more philosophical issues underlying evolutionary theory (which were still seen as connected to political values).

While Dawkins wanted to explain more closely the mechanisms of evolution, for instance complex design as an accumulation of small changes over a long time (e.g., the eye, Dawkins, 1996), Gould insisted on accounting for the actual evolutionary forces and levels of selection in nature, paying attention to potential constraints on adaptation. As Dawkins tried to explain the underlying neo-Darwinian reasoning, Gould demanded total realism. A number of popular books came out of this strange symbiosis.

Under this demand for realism, evolutionary psychology emerging in the 1980s could be treated in largely the same way as sociobiology. 'Ultra-Darwinians' became a handy umbrella term for both sociobiologists and evolutionary psychologists (Gould, 1997). Ultra-Darwinians were presented as being interested only in those mistaken adaptive explanations, while the 'pluralists' (Gould) or 'naturalists' (Eldredge) correctly appreciated the true processes of evolution. But later the sociobiological camp, fortified by the philosopher Daniel Dennett, increasingly started examining and rebutting Gould's various claims (e.g., Dennett, 1995; Maynard Smith, 1995; Alcock, 1998, 2001).

Value-Laden Science

Underlying the critics' scientific objection to what they called 'adaptationism' there was their old moral/political concern. If

everything is optimally adapted, there is no point in changing society. But instead of adaptation if you emphasize discontinuity, contingency (historical coincidence), and chance, you indicate that in a radically new environment new types of individuals will flourish. It is not a question of the selection of the fittest, everybody gets his chance (see Gould and Lewontin, 1979 for early expressions of such views).

Later Gould (1989) emphasized chance and contingency even more, arguing, for instance, that in the Cambrian explosion many different phyla existed which later went extinct. Humankind may never have come about. Gould also protested against the idea that evolution has a direction (going, for instance, toward greater complexity). He suggested making the humble bacteria the biological model species. Gould and Lewontin's overall strategy, then, seemed to be to develop the kinds of scientific arguments which, if adopted as social belief and if acted upon, would conceivably have politically desirable rather than undesirable social implications!

Interestingly, Wilson, too, pursued this kind of value-connected agenda at least part of the time. In *Sociobiology* he played down the significance of IQ and dismissed race as a useful biological concept. Later (in *On Human Nature*, 1978) he argued for universal human rights, "because we are mammals," and observed that "the long-term consequence of inequity will always be visibly dangerous." He advocated a more liberal sexual morality and defended homosexuality as socially useful. The social implications Wilson himself derived from his own theories were always liberal.

In the American sociobiology debate both sides pursued science and values together: they criticized undesirable science, derived values from science, and even put science in the direct service of values by trying to produce 'politically correct' science. In the United Kingdom, however, participants tended to adopt the exact opposite strategy: a strictly objectivist one, keeping science and values apart (e.g., Dawkins and Maynard Smith). Wilson switched between an objectivist and a value-laden stance depending on the issue.

A Changing Social Climate

In the 1970s and 1980s it was still too early for biologists to speculate about human nature without triggering an avalanche of protests from fellow academics. In the strongly pro-'culturist' academic climate, Wilson was not able to override his critics' interpretation of *Sociobiology* and convince people that this book was not meant as a political contribution. But this was soon to change.

Toward the end of the 1980s, a notable climate change was already under way. The post – World War II taboo on biological explanation of human behavior appeared to be broken. The importance of biological factors was increasingly recognized in many fields. More dramatically, the development of biotechnology and particularly the Human Genome Project were making genetics into a household word. 'Genetics' and 'behavior' were no longer seen as incompatible when it came to humans. If anything, there was an indulgence in 'gene talk' and ever new reports of genes 'for' behaviors such as 'thrill seeking' having been found.

A particular blow to the culturist paradigm came with Derek Freeman's attacks on Margaret Mead's studies of life in Samoa (Mead, 1928; Freeman, 1983, 1998). New studies documented the actual existence of human cultural universals (Brown, 1991). New research on language, culture, and later even morality, presented animals as much more similar to humans, resulting in popular books such as Frans De Waal's *Good-Natured* (1996) and Robert Wright's *The Moral Animal* (1994). The role of nonverbal communication was rediscovered as a fundamental link between nature and nurture and an important foundation for social life in both animals and humans (e.g., Segerstrale and Molnar, 1997).

A significant background event was the collapse of Marxism in 1989. More serious for the critics, however, may have been the 1980s unexpected shift within the 'academic left' itself, moving from its 1960s political activism toward a new postmodern left. That new 'cultural left' in academia showed little interest in traditional left-wing concerns such as science and ideology, or 'good' and 'bad' science, being now preoccupied with postmodern theoretical analysis and 'standpoint epistemologies' instead (Segerstrale, 2000b).

One factor dampening any new uproar around biology could have been the upswing in religious fundamentalism in the US. Evolutionary arguments could not be radically dismissed any longer unless one wanted to make common cause with conservative creationism.

A Broader Role for Sociobiology?

In *Consilience: The Unity of Knowledge* (1998), partly at least as his answer to the so-called 'Science Wars' in the early 1990s, Wilson gave sociobiology, or rather its genes – mind – culture version, a new and expanded mission. He identified gene – culture coevolution as the solution to the quest for the unity of knowledge and overcoming the Two Cultures problem for the benefit of all. The epigenetic rules were the needed tools for connecting the natural sciences with the social sciences and the arts. By bringing together different fields of knowledge they made it possible for us humans to perceive the world consiliently as a 'seamless web of cause and effect.' Among the epigenetic rules already discovered were universal color terms, genetic control of many behavior-affecting medical conditions, and biological constraints on esthetic preferences. More such rules would be found as science progressed.

Conflict About Cooperation

The sociobiological core research paradigm under its various names has no doubt been fruitful, giving rise to blossoming scientific industries: earlier especially around Hamilton's rule and kin selection, reciprocity, ESS, and evolutionary game theory, and later especially around newer models based on parasite – host coevolution, such as Hamilton's Parasite Red Queen theory for the evolution and maintenance of sex, and the Hamilton – Zuk hypothesis of health (freedom from parasites) as a criterion for sexual selection. Inventing clever strategies for avoiding parasites presented a stimulating challenge for the biological imagination and gave rise to

a plethora of empirical studies. The established explanatory framework turned out to be able to accommodate also unexpected findings revealed by new research; for instance, the intricate mixture of cooperation and conflict in the life of social insects. Kin recognition got serious attention, and behaviors earlier believed to be rare, such as spite, attracted new interest.

The theoretical core paradigm that had emerged from the groundwork by the founding fathers – Hamilton, Williams, Trivers, and Maynard Smith – seemed strong. There did not seem to exist a natural phenomenon that it could not handle; if anything, well-met challenges might be regarded as proof of the robustness of sociobiological explanation.

The regrettable deaths of main figures – Hamilton in 2000, Maynard Smith in 2004, and Williams, in 2010, – did not radically affect the research paradigm; the founders' former students and followers, eminent professors themselves, upheld the legacy of their mentors as they trained their own students and extended the field.

A decade after William Hamilton's death, however, a challenge appeared. In an article in *Nature*, in 2010, three Harvard scientists strongly advocated the abandonment of kin selection, the ruling paradigm for 40 years. According to these scientists, kin selection (identified with inclusive fitness) should just be substituted with regular natural selection theory instead. They argued that inclusive fitness was difficult to calculate and, as an approach, had not generated empirical results, while the theory of kin selection was not holding up in the light of empirical evidence. It seems that they saw the theory as dependent on the validity of the so-called 'haplodiploidy hypothesis' of the origin of eusociality, a complex form of social organization involving high levels of cooperation. (Haplodiploidy is a particular genetic inheritance pattern in social insects which gives rise to sisters being more closely related to each other – and their queen sister – than to their own hypothetical offspring.) Inclusive fitness solved the puzzle of sterility in social insects and explained how it made evolutionary sense for the workers to work for the queen instead of reproducing themselves. However, the idea that eusociality had something to do with the special condition of haplodiploidy, was only a sideline suggestion in Hamilton's (1964) paper. He introduced the social insect example only as an illustration of the idea of inclusive fitness, which was always intended to be a universal theory (see Segerstrale, 2013: chapter 11 for details).

The authors' suggested substitution for kin selection was group selection (or rather multilevel selection). They noted they had shown mathematically that under particular ecological conditions (such as the need for common defense) the cooperation of unrelated insects could give rise to eusociality. Therefore, for eusociality to emerge under these conditions, it would only require the appearance of an allele for cooperation. Genetic relatedness was not needed. The group consisted of E O Wilson working together with evolutionary game theorist Martin Nowak and mathematician Corina Tarnita (Nowak et al., 2010). Wilson saw the issue of insect eusociality as directly connected to the idea of the *Superorganism*. That idea he had recently revived in books written with Bert Holldobler, especially *The Superorganism* (2009).

The strong attack on kin selection met with a mass response from the sociobiological community in the form of letters to the editor of *Nature*, together signed by some 150 scientists (see e.g., Abbott et al., 2011). Kin selection was not an alternative type of selection, it was natural selection. Kin selection and group selection were not opposites, they could be translated mathematically into one another (as Hamilton had shown, based on Price). The paradigm had in fact been fruitful and generated an abundance of research. It did not exclude ecological factors; these could be part of the cost and benefit calculation in Hamilton's rule. Finally, the letter writers noted, the critics with their alternative models for the evolution of cooperation had not demonstrated that relatedness was not important just by leaving it out. The critics did not change their mind.

The challenge, however, may have had a positive effect. The mass response could be seen as a collective display of practicing sociobiologists informing the world and each other about their diverse contributions (as shown in the letters' lists of references). In this way the challenge would have had an integrative function for the field, similar to the integration of subfields that E.O. Wilson originally intended with *Sociobiology*. At the same time, it stimulated the exploration of a broader spectrum of models of cooperation and eusociality, and in this way a further expansion of the field.

Abstract

'Sociobiology' refers to the study of social phenomena as products of Darwinian selection. It has been the dominant approach to the study of animal social behavior since the late 1960s, although the term has fallen from fashion. Its principal architects were G.C. Williams, who persuaded biologists that selection produces adaptive attributes that serve the interests of individuals, not groups, and W.D. Hamilton, who expanded Darwin's concept of reproductive 'fitness' to encompass the individual's impact on the replication of her genes in both descendant and collateral kin. Essentially the same conceptual approach is now more often called 'behavioral ecology.'

'Sociobiology' refers to the study of social phenomena within the conceptual framework of biological science. More specifically, it usually refers to an explicitly neo-Darwinian approach that grew out of the theoretical contributions of Hamilton (1964) and Williams (1966). The hallmark of this approach is the interpretation of social behavior, and its causal mechanisms and processes, as products of the Darwinian processes of natural and sexual selection (*see* Darwinism), and hence in terms of adaptive function or 'design' (Dawkins, 1986).

Scope and History of 'Sociobiology'

The term 'sociobiology' was apparently coined by J. P. Scott, a student of the genetics and development of mammalian social behavior, who began organizing paper sessions on 'animal behavior and sociobiology' at scientific meetings around 1950. In 1956, the Ecological Society of America established a new section of 'animal behavior and sociobiology,' the forerunner of today's Animal Behavior Society, with Scott as its chairman (Dewsbury, 2000). However, the word 'sociobiology' was not widely used before 1975, when Harvard entomologist Edward O. Wilson made it the title of an ambitious volume reviewing and synthesizing information and ideas about the evolution of social behavior across the animal kingdom.

Wilson (1975, p. 4) defined sociobiology as "the systematic study of the biological basis of all social behavior," but although this definition is frequently quoted, it does not convey the word's meaning in actual usage. In the broadest sense, since 'biology' is defined as "the study of living organisms, divided into many specialized fields that cover their morphology, physiology, anatomy, behavior, origin, and distribution" (*Oxford On-line Dictionary*), and since only living organisms engage in 'social behavior,' Wilson's definition could be construed as inclusive of all social science. However, 'sociobiology' is obviously not used as a synonym for 'social science' and most social scientists do not consider themselves biologists. A narrower construction of the meaning of 'biology' does not help Wilson's definition conform to usage: for most scientists, the phrase 'biological basis' connotes the genetic, endocrine, and brain mechanisms underlying social behavior, but these 'proximate causal' factors are not the primary focus of sociobiologists, and most work in these areas would not be considered sociobiological. In practice, both Wilson's tome and subsequent sociobiological work have been primarily concerned with applying theories from population biology, genetics, and ecology to the problem of explaining the evolution of social phenomena and their diversity both among and within animal species (*see* Comparative Method in Evolutionary Studies), in much the same way as one might endeavor to understand the evolution and diversity of anatomical structures.

Like anatomists and physiologists, whose research is guided by their interpretations of the component parts and subsystems of organisms as devices 'for' digestion, respiration, vision, circulation of the blood, and so forth, sociobiologists are 'adaptationists' (*see* Adaptation, Fitness, and Evolution). That is, sociobiologists assume that social phenomena – such as mating preferences, offspring sex ratios, warning calls, systematically discriminative treatment of young by parents, situationally contingent gregariousness, seasonality of territorial defense, and so on – have a functional significance for the behaving animal that can be illuminated by appropriate hypothesis testing. Moreover, sociobiologists are 'selectionists.' That is, their hypotheses about the adaptive functions of social phenomena generally entail the assumption that the social attributes under consideration have been shaped by a history of Darwinian selection to be effectively fitness promoting in ancestral environments (*see* Adaptation, Fitness, and Evolution). Indeed, effective contribution to fitness (the replicative success of the focal individual's genes relative to their alleles, and hence genetic posterity) is considered the superordinate criterion of adaptive function; more immediate aims, such as foraging efficiently, attracting mates, and protecting one's young from predators, are interpreted as having evolved as means to the end of fitness.

Sociobiological theory and research began to flourish only after the fallacy of naïve group-level adaptationism or 'greater-goodism' (Cronin, 1991) was dispelled. For over a 100 years, Darwin's (1859) concept of 'natural selection' was widely misunderstood, even by evolutionary biologists, who often uncritically interpreted evolved attributes as having been selected to promote 'the reproduction of the species'.

Williams (1966) dissected and demolished this fallacy, persuading a majority of evolutionists that the capacity of Darwinian selection to create adaptive organization resides primarily in the differential reproductive success of alternative 'designs' within species, that the attributes that evolve therefore tend to be functionally organized to help individual organisms to outreproduce conspecific rivals, and that any ensuing benefits or harms to a whole population or species are incidental byproducts of organismic designs rather than what the designs are organized to achieve. This critique inspired a view of organisms as 'evolved reproductive strategists' whose attributes must be understood as tactics for effective reproductive competition against others of their own kind. (It is important to note that the 'strategy' metaphor carries no implication of foresight or intent. Indeed, the concept applies to brainless organisms as fully as to those with complex cognition. Thus, a sociobiologist might refer to a plant's 'reproductive strategy,' and decompose it into special-purpose 'tactics,' such as germinating in response to some degree of abrasion of the seed husk, flowering in response to a threshold air temperature, avoiding self-fertilization by asynchronous maturation of male and female flower parts, and so forth.)

The second main conceptual development leading to the flowering of sociobiological theory and research in the final third of the twentieth century was Hamilton's (1964) formulation of 'inclusive fitness' or 'kin selection' theory (*see* Kin Selection). Classical Darwinism had construed the fitness that selection tends to maximize as personal reproductive success, but Hamilton noted that selection will favor any phenotype (*see* Genotype and Phenotype) that effectively promotes the replicative success of copies of the focal organism's genes relative to their alleles (alternative forms of the same gene), regardless of whether those genes reside in descendants or in collateral relatives. Thus, for example, the complex brood care and colony maintenance behaviors of sterile worker ants can be favorably selected if these acts promote the reproduction of a queen who is closely related to the workers. Hamilton proposed that the quantity that selection tends to maximize is not personal reproduction (sometimes called 'direct fitness'), but the focal individual's 'inclusive fitness effect,' which is its total impact on the proliferation of its alleles via both direct fitness and any effects that the focal individual may have on the reproductive success of collateral kin (indirect fitness). Hamilton's analysis implied that organisms are not simply evolved 'reproductive strategists,' but evolved 'nepotistic strategists.' In this context, 'nepotism' means directing benefits to one's genetic relatives, and the implication of Hamilton's revision of the fitness concept was, to quote Alexander (1979, p. 46), that living creatures "should have evolved to be exceedingly effective nepotists, and we should have *evolved* to be nothing else at all." (Note that Alexander, like most evolutionary biologists, uses the word 'nepotism' to encompass acts that promote both the direct and indirect components of fitness; confusingly, however, some authors use this term to refer only to acts that promote indirect fitness, excluding parental care from its domain. Even more confusing is the common misuse of the term 'kin selection' as a substitute for 'nepotism,' such that an individual who is helping relatives is said to be exhibiting or engaging in kin selection. Used correctly, 'kin selection' refers to a population genetical process whose expected phenotypic consequence, on an evolutionary time scale, is nepotism, which is often but not necessarily manifested as selectivity in social response. Many sociobiologists, however, including Hamilton, have eschewed this popular phrase, both because it has so often been misused and because even its correct usage is often misinterpreted as logically parallel to, and theoretically alternative to, 'individual selection' or 'group selection'.)

In the late twentieth century, the word 'sociobiology' fell from favor, with most practitioners instead referring to their field as 'behavioral ecology.' This label has a slightly broader scope since it encompasses the adaptationist, selectionist approach to not just social phenomena but asocial behavior as well, especially foraging. Thus, although one might suppose from its title that the journal *Behavioral Ecology and Sociobiology*, established in 1976, would cover a broader domain than *Behavioral Ecology*, established in 1990, the scope of the two journals is identical. Declining use of the word 'sociobiology' should not be mistaken for a decline in the paradigm's popularity. Indeed, during the 1980s, the sociobiological approach came to dominate the study of animal social behavior, as it still does (Alcock, 2001).

The 'Problem of Altruism'

A central concern of sociobiological theory and research has been the 'problem of altruism': if Darwinian selection is a process that favors and refines only those attributes that contribute to their bearers' fitness relative to the fitness of conspecific rivals, then why is nature not more consistently 'red in tooth and claw'? In other words, how can such prosocial phenomena as restraint in aggressive conflict or active cooperation have evolved? In this connection, sociobiologists define 'altruism' as action whose average consequence is a reduction in the actor's direct fitness (expected reproductive success) and an increase in the direct fitness of someone else. (It should be noted that although this definition encompasses much of what might be deemed 'altruistic' in an ordinary English sense, since its essential feature is self-sacrifice that benefits others, it differs from ordinary usage in the fact that other-regarding intent is irrelevant.) At first glance, it would appear that selection must always penalize action that is altruistic in this technical sense, and yet animals often perform acts that clearly qualify, such as working to help raise others' young, or paying some energetic or predation risk cost in order to warn neighbors of danger. How these phenomena came into existence and are able to persist in a Darwinian world was a mystery before the 1960s, although the unexamined greater-goodism of many biologists kept them from recognizing that there was something in need of explanation.

Hamilton's inclusive fitness theory remains the most frequently invoked and most successful answer. If the beneficiary of an altruistic act is a relative of the actor, and if that relative's gain is sufficiently large relative to the actor's sacrifice, then the net inclusive fitness effect for the actor can be positive and the altruistic tendency can increase in its relative frequency. More specifically, Hamilton theorized that the necessary condition for a heritable altruistic tendency to increase in prevalence under selection (often called 'Hamilton's rule') is $r * b > c$, where c is the cost (in units of expected direct fitness)

incurred by the actor, *b* is the benefit (in the same currency) enjoyed by the altruistic act's beneficiary, and *r* is a 'coefficient of relatedness' between the actor and the beneficiary, indicative of the extent to which the two share identical genes by virtue of descent from recent common ancestors.

A great deal of sociobiological research has been concerned with testing whether altruistic behavior in nature can be understood as nepotism in accordance with Hamilton's rule (*see* Kin Selection). Supportive evidence has mostly taken the form of demonstrations that animals behave differently as a function of their relatedness to their interactants or neighbors. Animals such as colonial ground squirrels and prairie dogs, for example, have been found to call out warnings of predator presence facultatively, according to the potential caller's degrees of relatedness to others in the vicinity; similarly, adult animals usually provide costly care only to their own young (Daly and Wilson, 1988), and where this is not the case, parental 'helpers' still tend to discriminate with respect to relatedness to themselves (Griffin and West, 2003). There has also been considerable interest in elucidating how animals 'recognize' kin when they behave nepotistically (Krupp et al., 2011); in some cases, they respond to cues that are under more or less direct genotypic control, such as certain odors, and in others to reliable circumstantial cues (e.g., those who share my mother's womb with me must be close kin), while in still other cases there is apparently no direct discrimination at all but a 'rule of thumb' that achieves *de facto* discrimination (e.g., behave cooperatively until I emigrate at maturity, at which time my average level of relatedness to those that I encounter will plummet).

Theoretical sociobiologists have also sought nonnepotistic solutions to the problem of altruism, with particular interest in the circumstances that permit reciprocity (you scratch my back and I'll scratch yours) to be evolutionarily stable. This issue has been addressed primarily by game theoretical models, which have highlighted the necessity that nonreciprocators (cheaters) be detected and denied the benefits provided to reciprocators, as well as the difficulty of establishing the requisite punishment of cheaters in multiparty games, when punishing is itself a sort of altruism (i.e., the provision of a 'public good'). Empirical investigations of nonnepotistic reciprocity in nonhuman animals have been few, however, and claims of such reciprocity are open to alternative explanations (Clutton-Brock, 2009), perhaps indicating that the complex social cognition that is necessary for all but the most limited forms of reciprocation-in-kind is restricted to human beings and our near relatives.

Since 2000, there has been a resurgence of interest in theoretical models of natural selection among social groups. It is generally accepted, however, that 'multi-level selection' models and 'kin selection' models are mathematically equivalent, providing alternative perspectives on the same phenomena (Queller, 1992). Despite several attempts to unseat Hamilton's theory, it remains the cornerstone of theories of social evolution (Gardner et al., 2011; Queller, 2011).

Sexual Selection and Sexual Conflict

Another major focus of sociobiological theory and research has been sexual reproduction. Problems include when and why organisms reproduce sexually (i.e., biparentally) rather than uniparentally, and, in the event of 'dioecy' (the existence of two sexes with distinct adaptations), exactly how and why females and males differ. In 1871, Darwin (1871) supplemented his 1859 theory of evolution under the influence of 'natural selection,' by proposing a distinct evolutionary force that he called 'sexual selection' (*see* Darwinism). Whereas natural selection referred to the nonrandom differential reproduction of types as a result of differential success in coping with such exigencies as finding food, avoiding predators, and enduring climatic factors, sexual selection referred to the nonrandom differential reproduction of types as a result of differential access to mates and their reproductive labors. Darwin distinguished the two because they could sometimes act in opposition, as for example when sexual selection favors the evolution of conspicuous courtship structures, such as the peacock's tail, that enhance mating success but apparently also increase mortality risk.

Sexual selection was the object of scant theoretical or empirical work for a century after Darwin proposed the concept. Williams (1966) and Trivers (1972) resurrected it as a focal topic in sociobiology, proposing that the extent to which sexual selection operates differently on females and males, and thus produces sex differences in anatomy, physiology, psychology, and behavior, was determined by the extent to which the reproductive efforts (especially parental care) of one sex constituted the principal resource limiting the fitness of the less investing sex (usually, but by no means always, males), and hence the object of competition among members of the less investing sex.

More recent work has focused on the criteria and consequences of mating preferences (Andersson, 1994), and on conflicts of interest between the sexes that may lead to both antagonistic male- and female-specific selection pressures at the same genetic loci and sex-specific adaptations 'designed' to nullify one another (Arnqvist and Rowe, 2005).

'Selfish Genes' and Intragenomic Conflict

An area of great contemporary interest concerns the evolutionary consequences of the fact that selection can operate differentially on different components of the genome. Because the male sex-determining Y chromosome is transmitted only from father to son in such animals as fruit flies and human beings, for example, mutations on the Y that have the effect of biasing a progeny toward male production have been observed to increase in prevalence over generations, even when they reduce the inclusive fitness of the host individual. Conversely, mitochondrial DNA and other cytoplasmic inheritance factors are transmitted only from mother to daughter, and mutations in these factors that bias sex allocation toward females may similarly proliferate despite negative inclusive fitness effects. The consequence is 'intragenomic conflict': simultaneous selection at different genetic loci, within the same population, in favor of alleles with antagonistic phenotypic effects (Burt and Trivers, 2006).

The recent discovery of 'genomic imprinting,' a process whereby certain genes are differentially activated according to whether they were inherited from one's father or mother, has greatly extended the known potential for such intragenomic

conflict, as for example when genes of paternal origin are selected to produce fetal and infantile phenotypes that effectively 'discount' the value of the mother's potential future offspring (who may have distinct paternity) more steeply than do genes of maternal origin, leading to the evolution of directly antagonistic phenotypic effects of maternally and paternally imprinted genes (Haig, 2002). In a sense, these discoveries challenge the orthodox sociobiological view of organisms as nepotistic strategists with an integrity of purpose subsidiary to the function of maximizing inclusive fitness, since selection clearly can and does favor the proliferation of genes that promote their own replication at the expense of 'their' organisms' inclusive fitness. However, the individual-level focus of sociobiological research continues to be productive (Alcock, 2001) and is unlikely to be abandoned soon.

This article is a revision of the previous edition article by F. Geyer, volume 21, pp. 14549–14554, © 2001, Elsevier Ltd.

Abstract

The article outlines the origin of sociocybernetics and its roots in systems science and cybernetics. It explains key concepts of first-order cybernetics, the cybernetics of observed systems, and second-order cybernetics, the cybernetics of observing systems. Central issues in the latter are organization, self-organization, and autopoiesis, all based on circular causality. The epistemological foundations in constructivism are exposed, which are closely related to the problem-oriented interdisciplinary approach inherent in systems science, cybernetics, and sociocybernetics. The article concludes with an argument for the relevance of sociocybernetics as a social science of complexity in the contemporary global and dynamic world.

The Concept and Its Origin

'Sociocybernetics' is a term belonging to a whole family of related terms like 'cybernetics', 'systems and cybernetics', 'systems theory', 'general system theory', 'systems approach', 'systems research', '(applied) systems analysis', 'systems methodology', 'systems thinking', 'systems philosophy', etc. Here, we cannot go into the details of these variations. Instead, we concentrate on 'systems' and 'cybernetics,' which are the key concepts. In general use, they are frequently interchangeable or appear in combination (e.g., in the names of WOSC – World Organization of Systems and Cybernetics and AFSCET – Association Française de Science et des Systèmes Cybernétiques, Cognitifs et Techniques). Hence they can be considered as synonyms like in this contribution, although the two terms come from different traditions and are not used uniformly in different languages and different national contexts.

Sociocybernetics is defined as 'systems science in sociology and other social sciences', whereby 'systems science' includes 'cybernetics'. The term systems science was chosen because 'science' is not limited to theory. It includes application, empirical research, methodology, axiology (i.e., ethics and value research), and epistemology (Geyer and van Dijkum, 1999: pp. 11–28). The term 'sociocybernetics' was first used as title of a book published by Felix Geyer and Johannes van der Zouwen (1978). The use of systems science and cybernetics in the social sciences dates back much further of course, even to the very roots of cybernetics like Norbert Wiener's book on *Cybernetics or Control and Communication in the Animal and the Machine* (1948 also 1956), whereby the 'animal' includes the human being and communication is not just a technical but also a very social phenomenon. A second root, on the systems side, is biology (Bertalanffy, 1968).

Under the name of 'sociocybernetics', however, systems science has made its way into the International Sociological Association (ISA) since 1980 and was firmly established as an ISA Research Committee at the 1998 World Congress of Sociology in Montreal (Geyer and van der Zouwen, 1986; Geyer, 1997; Marcuello Servós, 2006).

Systems, Cybernetics, and Circular Causality

Certain systemic or cybernetic aspects have been present in the social sciences since long. In a way, Marx can be considered a systems theorist just like Durkheim with regard to other aspects and, of course, Talcott Parsons. Sociocybernetics is different from these approaches as it strives to make full use of the complete set of theoretical and methodological tools systems science and cybernetics provide, which have flourished and spread since the Second World War (cf Buckley, 1968).

This means that sociocybernetics includes both so-called first-order cybernetics and second-order cybernetics. According to definition, cybernetics is the science of 'control and communication in the animal and the machine', including human beings and natural 'machines' (Wiener, 1948). This provides already a bridge between the natural sciences and the social sciences, which nowadays is broadened and developed, e.g., by human ecologists. Heinz von Foerster (von Foerster, 1981; von Foerster and Poerksen, 2002) went on to distinguish a first-order cybernetics, 'the study of observed systems', and a second-order cybernetics, 'the study of observing systems' or the 'cybernetics of cybernetics' (von Foerster, 1970). Second-order cybernetics is different from first-order cybernetics in two fundamental aspects. First, it is explicitly based on constructivist epistemology and second, one of its main concerns is self-reference and self-organization, including the autopoiesis of living systems. Second-order cybernetics pays particular attention to the observer dependence of knowledge, including scientific theories (cf Hornung, 1995, 2006). In the interdisciplinary spirit of systems science, sociology is clearly at the center of interest of sociocybernetics. The other social sciences, however, like psychology, anthropology, political science, etc., need to be included too, depending on the research question to be dealt with (Hornung, 2002, 2004, 2006).

This does not mean that first-order cybernetics and its basic concepts can be discarded and ignored by the social scientist. They are basic also to second-order cybernetics. Furthermore, systems science and cybernetics, and hence sociocybernetics, are intrinsically problem oriented. This means that it is a question of the problem at hand, whether for a given research

problem first- or second-order (socio)cybernetics is more appropriate.

A system can be defined as a whole consisting of interdependent components. Basic to any sociocybernetic approach, are the four key concepts which define a dynamic system (Laszlo, 1973):

1. The holon property: A system is more than the sum of its parts and has properties different from those of the individual parts. This also implies a boundary which distinguishes the system from its environment and which can be more or less closed. In the social sciences, it is often difficult to determine the boundary of such a 'unit' of research, because social systems, groups, e.g., often have very open boundaries which makes them difficult to define and to identify.
2. The systems hierarchy: This is not a hierarchy of command but a hierarchy of structure. Every system has parts, i.e., subsystems, and every system is embedded in a larger system. Whether the largest system, the universe, is indeed a system, can be disputed, because its boundary cannot be identified. At the other extreme, the search for the smallest system in the subnuclear sphere is still going on. Social systems are at a mesolevel between these extremes of natural systems. For analyzing systems and for acting in systems, this means that there is always a wider picture but also a narrower one.

These are structural aspects of systems. Two more basic properties refer to processes as follows:

3. Negative feedback: Here negative (or positive) does not imply any normative connotation but simply indicates the direction of an effect. Negative feedback in a chain of cause and effect means that an effect is produced which counteracts the initial cause, i.e., in the end diminishes the effect (negatively). Therefore, it is also called 'deviation reduction'. An example is the thermostat or in social systems negative sanctions, e.g., by legal authorities.
4. Positive feedback: A cause is producing an effect which in the following time step influences the cause in a way that it gets stronger. There is a deviation amplification. This, e.g., is the case of an avalanche in nature or of positive sanctions and reinforcement in social systems. In abstract terms, any case of exponential growth is technically a case of positive feedback, which from a normative point of view may not be positive at all.

The feedback implies circular causality of some sort and the concept of interdependence of parts or subsystems implies long causal chains with many bifurcations. Although the system boundary delimits the area of causes and effects, boundaries are usually not completely closed or they are closed only for certain exchanges. The controversy of open systems (Bertalanffy, 1968, Network) vs closed systems, which are professed in the social science, e.g., by Niklas Luhmann (1995), is by no means resolved. It may be considered another case for the problem-oriented approach. In a similar way, the systems hierarchy is a limiting factor for the spreading of effects. But also the hierarchy is not completely closed and permits upward and downward causality along with phenomena of emergence (Buckley, 1998).

With these concepts, sociocybernetics pushes the social scientist to become aware and to pay attention to long-term effects and side effects of events, actions, or measures taken. These effects include complex feedbacks along many pathways and across many bifurcations. In the end, these may lead to a dramatic positive feedback and amplification of the initial event or also to neutralizing and blocking any effect of even a major effort. Examples for both cases can easily be found in politics and its projects. Sociocybernetics thus provides useful theoretical tools to analyze such phenomena, even using 'only' first-order cybernetics.

Circular causality can be purely mechanical, a structural arrangement of causes and effects amplifying or neutralizing each other, but it also may involve information processing which, in a very simple way, is already present in the thermostat. Temperature is measured, 'observed,' the result is compared to a preset target value, and this comparison determines the reaction – increase or decrease temperature or no reaction. As simple as such information processing is in the thermostat, as complex it is in the human brain and psychological system or in modern societies with their complex institutions of parliaments, governments, administrations, etc.

At this point, second-order cybernetics enters the picture. The research object of the social scientist is not a (mechanical) object anymore investigated by a detached researcher. Instead, it is taken into account that the researcher influences his object of research being part of the (overall) system and not outside. Moreover, the object in its turn is an observing system. With regard to human beings with their psychological and cognitive capacities this is quite evident. In terms of a systems hierarchy, the latter can be seen as cognitive and psychological systems embedded in larger over-arching systems. Taking this into account, sociocybernetics leads away from a Durkheimian view of society as a large mechanism or organism, in which the individual is a small wheel, or from the Marxian view of society as an anonymous big 'system', which determines the life of its victims. Instead, it suggests an actor-oriented view (Kuhn, 1974; Etzioni, 1968; Burns et al., 1985). The social individual with his cognition is conceived as an observer and actor observing and interacting with other observers/actors. These are not necessarily other individuals. They can be social units like groups and organizations which have a capacity for (collective) information processing or also for knowledge and meaning processing. Knowledge can be defined as a network of interrelated information and meaning as knowledge related to goals and values (Bossel, 1998, 1996).

The basic concepts of systems and cybernetics still remain the same, but observation and information/knowledge/meaning processing are added. The recombination of all of this provides a highly complex picture of what are social systems and societies from a sociocybernetic point of view (cf Andreewsky and Delorme, 2006).

Systems, Actors, Steering, and Control

Cybernetics, much more than systems science, is closely associated or even identified with the concept of control, which in ordinary language has a mostly negative connotation. In systems science and cybernetics, however, it is used in a technical sense and as a complement to the concept of steering. Both steering and control, also called feedback and feedforward, are based on circular causality at a level which includes

information processing. They are basically the same process, but feedback reacts to an event that already happened. It is an attempt to change its consequence. Feedforward 'reacts' to an event which is only anticipated. It produces an effect that avoids an anticipated event. Steering a car or a ship – the term 'cybernetics' has its origin in the latter – is clearly based on anticipatory action. There is no point in steering anymore, once the car is after a curve in the field already.

Steering and control usually do not refer to the in-built 'natural' cycles of feedback in a system but to special steering or control units (cf Burns and Buckley, 1976). The main causal chains involved in the operation of such steering and control units – not to mention the (unintended) long term and side effects – are not necessarily limited to one particular subsystem. They can cut across several subsystems and several system levels, as can be seen easily in any large organization (cf Beer, 1972). This means that mechanisms and effects of steering and control in a system need to be clearly distinguished from feedback loops which kind of naturally result from the structure of a system and which frequently even operate behind the backs of the social actors. Hence sociocybernetics does not conceive of social systems and society as mechanisms enforcing their intrinsic laws against the individuals or as mere collections of individuals, i.e., social actors. Instead, they are seen as interactions of systemic structures and processes with social actors. The structures certainly confine and delimit but also enable social action, while the actors also change and modify the larger system which is their environment. Therefore, sociocybernetic theory is neither a pure 'system' theory at the macrolevel nor a pure actor theory but an actor–system theory or actor-oriented approach (Burns et al., 1985), whereby the actor himself is a particular kind of system too.

Organization, Self-Organization, and Autopoiesis

While steering and control are tools for organizing systems, the actor-oriented approach raises the question of the limits to (intentional) organization and self-organization. Organization, from a systems and cybernetic view, is the buildup of negative entropy (negentropy), i.e., of a more improbable state than the equal distribution of matter and energy. This concept comes from thermodynamics originally (Prigogine and Stengers, 1984) but can be used for symbolic and informational structures as well (Bailey, 1990; Stonier, 1990), which always depend on a physical medium, be it a brain, a computer or the paper of a book. Consequently, the concept of entropy and negentropy is also applicable to social systems and sociocultural systems, which are to a considerable extent symbolic and informational (or also conversation (Pask, 1975; Scott, 2011) and communication (Luhmann, 1995)) systems. Building up improbable states, i.e., structures, of matter/energy and information, however, is only one part of the story.

The other part is the persistence or sustainability of such structures (and processes), which, after all, constitute systems. The social sciences are usually dealing with dynamic systems. To be sustainable (or viable), they cannot exist with just any structure. Their structure needs to fulfill certain functions which permit survival in a dynamic environment (Bossel, 1996, 1998). This means to be able to react adequately (by steering and/or control) to influences from the environment which is apt to disturb the viability. This is possible only, if a system disposes of enough variety of possible reactions to the variety of influences, disturbances, or inputs from the environment – however, one wants to call them. This was formulated by Ross Ashby (1956), one of the fathers of cybernetics, in his 'Law of Requisite Variety'. In a somewhat different way, this was reformulated by Niklas Luhmann (1995: p. 26f) in the context of his complexity theory: Only (system) complexity can reduce (environmental) complexity.

This suggests a functional approach to social systems. Indeed, much of sociocybernetics and its predecessors is functionalist (e.g., Parsons, 1966, 1967, 1971; Luhmann, 1995). In applied systems analysis and applied sociocybernetics, it turns out, however, that a functional view is not enough. Also units have to be taken into account, which often have the same set of functions, e.g., communities, states, countries, etc. One of the few systems theorists who explicitly followed the unit approach was James G. Miller (1978). In applied and empirical sociocybernetics, leaving the theoretical level, the two perspectives need to be combined. This has barely been attempted on a theoretical basis. Kenneth D. Bailey (1994) proposed to integrate both views, of social units and of variables resp. functions, using Q–R analysis which comes from psychology.

In this framework, the units, in psychology usually the individuals, constitute one dimension (Q) and the variables/functions constitute a second dimension (R) which cuts across the individuals orthogonally. All of them have the same kinds of properties identified by means of variables/functions.

From this point of view a real-life system, e.g., an organization, is a unit incorporating a set of functions which permits it to survive and to be viable/sustainable in a changing environment. Organizing a system means to set up structures and processes which provide a greater variety of action and reaction – in terms of Ashby's Law of Requisite Variety – or, in Luhmann's terms, more system complexity to better cope with the environmental complexity.

While 'organizing' refers to an intentional effort of an actor to achieve this, 'self-organization' refers to a circular process of buildup of structures and processes which is not the result of the activity of one (central) actor but an unplanned and unplannable process. Such a process is determined by the interactions of several actors inside the system and interactions of those actors with the system structures and processes in which they are embedded.

Similar considerations like for social action hold for information processing (knowledge processing, meaning processing (cf Stonier, 1997)) at the symbolic level. This includes also communication. At the symbolic, cognitive, level, however, the concept of self-reference is used.

Self-organization and self-reference are based on circular causality just like a third concept, autopoiesis. This constitutes still another level of complexity. The theory of autopoiesis was originally developed by Humberto Maturana and Francisco Varela (1980), two Chilean biologists, seeking to explain what is life. They call the process autopoiesis by which a living system produces the very components of

which it is composed out of its own components. An organism uses its own cells to (re)produce the same kind of cells and to stay alive in this way. To do so, it needs matter/energy from outside, which it can transform into cells, i.e., there is a metabolism. At the level of information, however, there is no such import of information. According to Maturana and Varela living – autopoietic – organisms are informationally closed. They react to disturbances, but there is no inflow of something called information.

Niklas Luhmann modified the concept of autopoiesis to apply it to social systems. Whether this is legitimate and whether social systems are to be considered living systems remains disputable, however.

Problem Orientation Based on Epistemological Constructivism

The questions whether the concept and theory of autopoiesis is applicable to social systems, what is 'an actor', e.g., inside an organization, and what are the boundaries of the system under consideration (the 'reference system') show that the answers are not necessarily evident. Also the question can be raised, whether systems do exist indeed.

Systems theory and cybernetics have two answers to these problems.

Early systems theory and cybernetics tried to resolve such issues by resorting to an epistemological nominalism. This means that systems are not considered as entities existing in the empirical real world, but as scientific concepts which permit to consider all kinds of real-world phenomena as systems in order to do the corresponding research and analysis. This, not very satisfactory, epistemological approach was replaced by an epistemological constructivism. In the systems and cybernetics community, this was professed in particular by Heinz von Foerster (von Foerster, 1981; Müller and Müller, 2007). Constructivism, although not under this name, can be traced back in the philosophical tradition to Husserl, Schopenhauer, and Kant.

Epistemological constructivism asserts that 'things' are not ontologically given as such (which would be realism). However, it also asserts that they are not mere inventions of human thinking without any relation to an outside 'real' world (which would be idealism). Instead, constructivism asserts that something exists, which cannot be perceived, however. It is the perceiver or observer who names certain phenomena according to his convenience and who constructs his perceptions and cognitions. These constructions, however, are not arbitrary, as they have to prove their validity in practical tests of practical life. This view corresponds very much with the paradigms of Thomas S. Kuhn (1962), who says that a paradigm or also a scientific theory is neither true nor false but only more or less useful.

In a way, epistemological constructivism overcomes the Cartesian dualism. It can also be found in the work of the Mexican scientist Rolando Garcia (e.g., 2000, 2006), in the autopoietic theory of Maturana and Varela and, with certain reservations, in the sociological theories of Niklas Luhmann. The latter was strongly influenced by von Foerster, Maturana and Varela, and also by Edmund Husserl. A recent impulse to the development of constructivism was given by Arne Kjellman (2002, 2003) with his epistemological theory on subjectivism and the priverse.

Sociocybernetic Methodology

The fundamental constructivist approach is also reflected in the problem-oriented methodology frequently used in sociocybernetics. The basic idea is that the object of research is not determined by the givens of existing reality out there but by the research question or research problem. This determines which slice of empirical reality needs to be investigated to resolve such a reference problem and also which disciplines need to be involved. In other words, sociocybernetics is inherently interdisciplinary by its methodology.

Stating the reference problem and the corresponding reference system makes clear what are the relevant functions to be considered, which are the mechanisms or units fulfilling such functions, what is the environment, which are the subsystems, etc. Only then it can be meaningfully stated what is functional, dysfunctional, functionally equivalent, etc., also which structures may be functionally equivalent, thus avoiding the Parsonian conservatism. A systematic picture of this multidimensional theoretical apparatus is given by Hornung and Adilova (1997).

A problem-functionalist approach has a second advantage. It permits from the very beginning to include normative or axiological issues (cf Parra-Luna, 2000). After all, the concept of 'problem' itself has both a factual and a normative component. A problem is a state of affairs (a fact) which needs to be changed (a normative request).

To carry out systems and cybernetic research, computer modeling and simulation can be considered as the paradigmatic method in the sense of Thomas S. Kuhn (1962). With regard to sociocybernetics, however, it needs to be pointed out that social systems are barely suitable for computer modeling for quite a number of reasons which cannot be discussed here (cf van der Zouwen, 2006). Suffice to mention the problem of enough and consistent data to cover an entire model of a social system. However, modeling in general, from a sociocybernetic perspective, covers the whole range from mental or conceptual models to fully quantitative computer models. Conceptual models may be formulated in the form of texts or diagrams (cf Checkland, 1981; Checkland and Scholes, 1990), while qualitative models can be computer based (cf Bossel et al., 1989). Fully quantitative models can be of the Forrester type (systems dynamics models (Forrester, 1968, 1971)) or scenario models as originally developed by Meadows et al. (1972; Meadows and Robinson, 1985; Mesarovic and Pestel, 1975).

Beyond this, empirical and applied sociocybernetics can use any method of empirical research which is scientifically acceptable and suitable to obtain the data desired.

Sociocybernetics – Social Science of Complexity

Science is not just an end in itself but plays a major role in human life, from microbiology and genetics to globalization

and the warming of the planet. The social sciences might be expected to play an especially important role in the organization of social systems and the solving of their problems. Major problem lines of human society can be mentioned here briefly only. Some of them are old, some of them new, all of them are shifting, complexifying, and a few maybe dissolving. The ideology-based conflict between East and West with the Soviet Union has disappeared; the conflict North–South has been changing its character moving toward a more general poverty gap also inside the Western most modern countries. It has given way to what Huntington (2002) calls the 'clash of civilizations'. Overarching remains the conflict between man and nature – the ecological problems – and the problems resulting from globalization.

New kinds of problems are appearing – or at least become evident – at the individual level inside our social systems: psychological disease, depression, burnout, and sectarianism – the market of all kinds of religions. Exploitation, the traditional Marxist concern, is becoming replaced or rather complemented by self-exploitation. In other words, a new kind of alienation has appeared (for a sociocybernetic account of alienation, cf Geyer, 1980). At the root of this seems to be the loss of traditional certainties in combination with an increasing unmanageability both of social systems and of individual life. This in spite – or also because? – of all the progress in science and technology (cf Aguado et al., 2009).

In abstract terms, the ever increasing tremendous complexity of society and its technologies together with the ever accelerating speed of change – social and technological dynamics – risk to strain human capacities beyond their limits and to make the world inhabitable, both physically and psychologically.

Systems science and cybernetics in general and sociocybernetics in particular promise a framework which might be suitable to tackle these issues – at any rate, a better one is not in sight. While the theoretical apparatus seems adequate to build up enough theoretical complexity to cope with the world's complexity, the methodology, in the field of sociocybernetics, remains still insufficient. The question of data can be resolved only partially in specific cases and selected instances. Methodology and data, however, might not be problems of sociocybernetics but result from fundamental properties of the objects we are dealing with: social systems and human action at the level of second-order cybernetics.

In this respect, the ambitions and aspirations of sociocybernetics as a social science of complexity may be, as Johannes van der Zouwen (2006) expresses it in the subtitle of his article, indeed 'a bridge too far'.

Abstract

The purpose of this article is to review what engages *digital natives*, i.e., children and adolescents who have, from the beginning of their lives, been socialized to use sociodigital technologies. Surveying the research literature, we present findings as to what pursuits digital natives find interesting, motivating, and involving in both informal and formal learning environments drawing upon motivation theories of flow and engagement. Our conclusion, in this article, is that adolescents' ways of engaging in using digital technologies are heterogeneous; a minority of young persons has access to parental or peer support and facilitation that engagement in creative use of digital technologies together with their own motivation and efforts may require. Although sociodigital technologies facilitate creating and maintaining extended networks, cultivating technological fluency, and participating in passionate interest communities and networks, there are worrisome trends; these include 'addictive' use of technology, fragmented processing of information, and 'digital divides' between creative and educational use of sociodigital technologies.

Introduction

The purpose of this article is to review the pursuits that engage digital natives intellectually, emotionally, and socially (Prensky, 2001, 2012; Palfrey and Gasser, 2011). *Digital natives* are adolescents who have from the very beginning of their lives been socialized to intensive use of sociodigital technologies (i.e., integrated systems of technological tools, social media, and global information networks that support collaborative creation and sharing of activities, media, and knowledge). Prensky (2001) claimed that there is a profound discontinuity between engagement of the young people who have been immersed in sociodigital technologies from very early in their lives and the so-called *digital immigrants*, for instance, their parents and teachers, who have learned to use digital technologies in adulthood, if at all. At the age of 20, many Western adolescents have accumulated 10 000 h of computer or game console use, 10 000 h of mobile use and exchanges, and 200 000 received and sent e-mails and instant messages (Prensky, 2012: 78). Presumably because of extended socialization to use of sociodigital technologies, there appears to be a special relation between young people and various digital technologies that differentiates them from the older generations. Accordingly, adolescents are often very comfortable with various sociodigital tools and applications and able to fluently learn novel applications. They are thought to be used to more extensive multitasking and to be more effective in task switching than their parents and teachers while handling the intensive digital information and media flow (Palfrey and Gasser, 2011; Prensky, 2001). This possible generational gap should, however, be studied properly in controlled experimental setups. In any case, whenever young people have a problem, they seek help via the Internet whereas older participants still more often consult books and go to libraries. Rather than relying on traditional physical books and handwriting, digital adolescents constantly process virtual information on the screen. Being online is an integrated part of their daily life and they do not appear to experience a similar difference between online and off-line realities than older generations do (Ito et al., 2010). Further, at least a half of the young people are estimated to have taken part in such creative processes as creating media content and one-third of them have shared some personally produced content through the Internet (Jenkins et al., 2009; Lenhart and Madden, 2005).

According to Thomas (2011: 4), the discourse on digital natives typically involves three interrelated assumptions: Digital natives constitute a largely homogeneous generation and speak a different language vis-à-vis digital technologies from that of their parents, the digital immigrants; they learn differently from preceding generations of students; and they demand new ways of teaching and learning regarding technology. A number of investigators, however, have questioned one or more of these assumptions; indeed, the whole notion of digital natives has been said to be problematic; some have argued that the digital competencies of the young generations have been seriously misjudged (see e.g., Bennett et al., 2008). Most young people use sociodigital technologies only for everyday recreational purposes and do not have any of the claimed sophisticated competencies of alleged 'digital natives.' In many cases, differences between young people's digital competencies appear to be larger than differences between the younger and older generations (Jenkins et al., 2009; creative participation gap). There are considerably many representatives of older generations who have acquired high-level digital competencies (Bennett et al., 2008). Moreover, many educational researchers (see e.g., Jenkins et al., 2009) are more concerned about the differences among the digital natives and the underlying individual and contextual factors behind them. It is arguable that, so far, the discourse of digital natives has not been grounded on well-established empirical evidence (Bennett et al., 2008);

 http://dx.doi.org/10.1016/B978-0-08-097086-8.26094-7

instead, one sees numerous problematic claims that have not been empirically verified.

We argue that the concept of the *digital native*, although controversial, is a useful working hypothesis for addressing the profound impact of sociodigital engagement on intellectual and socioemotional activities of young people. The evolutionary significance of the extended human childhood and adolescence is in allowing new generations of humans to adapt to a radically different environment from that of the older generations (Wexler, 2006). The earlier and the more intensively one adapts to the cognitive, social, and cultural 'prostheses' (Clark, 2003; Donald, 1991; Ritella and Hakkarainen, 2012) provided by the use of continuously present sociodigital technology, the stronger their impact on a young person's intellectual, emotional, behavioral, and social engagement is likely to be. To acknowledge developmental effects, we do not have to assume that adolescents' engagement in using sociodigital technologies is uniform; our approach is to examine, with a person-oriented approach, how various populations of youth use sociodigital technology and their associated motivations. Although the concept of the digital native is in many ways problematic, it may be taken as a provisional tool for addressing various issues that appear relevant to understanding adolescents' learning and engagement.

The purpose of this article is to review the literature concerning digital natives' engagement in their chosen pursuits, within the framework of theories of flow (Csikszentmihalyi, 1996; see chapter by Nakamura & Dubin) and academic emotions (see chapter by Pekrun; also Inkinen et al., 2014). In the first section we present findings on adolescents' engagement in using sociodigital technologies to 'hang out' with their friends. The second section focuses on findings concerning adolescent's engagement in using sociodigital technologies to pursue their interests. Section three compares the digital divides between adolescents who engage only in shallow use of sociodigital technologies and those who have access to instruments, practices, and support that creative engagement in using digital technologies requires. Finally, we will address limitations of our current understanding of digital natives as well as outline fruitful lines of deepening inquiry in the area.

How Hanging Out with Peers Engages Adolescents

Rather than assuming uniform generational differences, investigators would do well to examine patterns of engagement of various populations of adolescents in using sociodigital technologies (Helsper and Enyon, 2011; Palfrey and Gasser, 2011); we maintain that a person-oriented approach (Laursen and Hoff, 2006) is fruitful. Ito et al. (2010) carried out a year-long ethnographic investigation of digital youth's engagement in using sociodigital technologies, distinguishing three levels of engaging in technology-mediated activity, i.e., (1) friendship-driven use of sociodigital technologies for 'hanging out' with peers, (2) interest-driven 'messing around' with technology and media that is oriented toward developing associated skills and competencies, and (3) 'geeking out' for seriously cultivating expertise related to digital technologies or creative working with media. The proposed notion of adolescents being driven by either friendship- or interest-related aspects resonates strongly with the results of recent studies (Eynon and Malmberg, 2011; Kennedy et al., 2010) that have addressed the variation in adolescents' sociodigital activities. These investigations, despite some diversity in the methods used in them, share the key finding that the largest group of adolescents engages mostly in friendship-driven activities, and only a small minority participates frequently in more demanding, interest-driven activities.

More than 90% of adolescents in the Western countries have access to the Internet and recent study showed that 63% of them use sociodigital technologies once or several times a day for connecting with their friends and family members (Madden et al., 2013). They use mobile devices and social media applications to constantly keep up networking connections with their friends and to strengthen their face-to-face relations and sense of belonging with their peers (Ito et al., 2010). Three-quarters of adolescents are mobile Internet users in terms of using smart phones, tablets, or other mobile devices (Lenhart et al., 2010; Madden et al., 2013). This allows active participants to be in continuous connection with their friends through constant instant messaging, and lurking and commenting on friends' activities within social media. Virtual communication allows them to be together even when separated from one another temporally (e.g., evenings) or spatially (e.g., being out of their neighborhood when visiting relatives). Besides lurking and updating one's own status the friendship-driven activities rely on giving constant feedback (e.g., 'likes') to each other's updates and expecting social recognition in return. Sociodigital networks constitute an essential aspect of the social operating system of adolescents (Rainie and Wellman, 2012) determining the modality of connection, the nature of information exchanged, ways of collaborating, and so on. A decade ago, only a quarter of Finnish upper elementary school students reported using computers daily (Hakkarainen et al., 2000). Currently, many adolescents report having digital contact with their friends several times a day or having a continuous connection (e.g., 61.2% of elementary school sixth graders report *chatting* at least daily (36.6% several times a day or 'all the time') and 48.8% report using *social media services* at least daily (23.8% several times a day or 'all the time')). (The situation of young people's practices of using sociodigital technologies is rapidly changing. The numbers presented in this paragraph rely on data collected in 2013 from Finnish sixth grades across 33 schools of Helsinki, Finland.)

Beyond the intensity of keeping up networking contacts, the nature of adolescents' social networks is also changing (Gee and Hayes, 2011; Ito et al., 2010; Rainie and Wellman, 2012). Various applications of social media presently allow young people to keep up more extended and far-reaching networks than used to be the case. Adolescents who move from one school, neighborhood, city, or country to another, are able to keep up their friendship relations to an extent that was not possible before. Many adolescents have a very extensive network of 'friends' (these are connected persons, including acquaintances; according to Facebook 2012 statistics, an average Facebook user has 130 Facebook 'friends'; according to Madden et al. (2013) teens have an average of 300 'friends'). Currently, however, young people appear to be

moving from just building huge networks of designated 'friends' toward maintaining their social networks and web privacy in a new way and separating their public networks from their private (e.g., Madden et al., 2013). Some say this is due to the increasing presence of adults and family members in e.g., Facebook and the related difficulties of controlling their privacy.

Being in a constant networking connection is likely to make socioemotional regulation of activity become socially distributed. Many aspects of adolescents' lives are being collectivized by moving to the virtual network, including creation, keeping up, and breaking intimate relations (Ito et al., 2010). Young people often meet their intimate partners through the 'net' and publish their relationship status in social media. Beyond the sharing of positive emotions with peers, also negative emotions and frustration may spread through social networking connections. Simultaneously with providing a sense of relatedness, social media could make a young person to become obsessed with self-presentation in social media, compulsively following status updates of his or her contacts and managing impressions (Nadkarni and Hofmann, 2012). If participation in the virtual world replaces building of social relations and limits interpersonal encounters and interaction, it may lead to reduced well-being, disengagement, increased anxiety, and depression. The emergence of social media has made it clear that rather than leading to social isolation, intensive use of sociodigital technologies is usually embedded in a rich network of both online and off-line social interaction (Rainie and Wellman, 2012). The sociodigital technologies are, however, transforming so quickly that no one has clear understanding of the psychosocial impact and consequences of adolescents' engagement.

Interest-Driven Engagement with Sociodigital Technologies

When adolescents use sociodigital technologies to pursue their interests, they are 'messing around' or 'geeking out' with technology (Ito et al., 2010). The former is motivated by sharing interests, whereas the latter one involves enhancing competence and cultivating expertise; this has made some investigators enthusiastic about the positive impact of sociodigital technologies on adolescents' learning and development (Barron, 2006; Gee and Hayes, 2011; Ritella and Hakkarainen, 2012). Adolescents who become engaged in technology-mediated activities often start experimenting, with various technological tools and applications relevant to their interests. This 'messing around' represents, in turn, a transition zone between friendship-driven 'hanging out' and interest-driven 'geeking out' (Ito et al., 2010). It involves intensive engagement with digital technologies for sharing interests related to sociodigital technologies, for example, playing computer games or sharing and producing media. Different levels of digital participation may be distinguished, ranging from mere observation and follow-up to personal participation in creating and building media (Gee and Hayes, 2011; Ito et al., 2010; Jenkins et al., 2009).

Some adolescent are 'geeking out' (Ito et al., 2010) in terms of diving very deep into the sociodigital world and becoming experts in using sociodigital technologies, often being highly regarded among adolescents (Hakkarainen et al., 2000). They have appropriated sociodigital tools that allow, for example, modifying, remixing, and mashing up artifacts created by selecting, cutting, enhancing, filtering, and transforming media elements (Gee and Hayes, 2011; Ito et al., 2010); this requires new far-reaching network connections with persons who share the same interest. 'Geeking out' may thus involve a trajectory of actively cultivating technological competencies (Gee and Hayes, 2011), for instance, in terms of creating media objects (videos, pictures, music), modifying virtual environments ('modding' game environments), programming (creating new applications), or constructing technological systems (building robots).

Expert knowledge is now accessible to Internet users to an unforeseen extent, without requiring formal credentials (Gee and Hayes, 2011; Rheingold, 2012). Many adolescents cultivate their expertise by meeting more competent peers as well as with adult experts interested in similar issues on the Internet (Shirky, 2010; Rheingold, 2012). They may start functioning as 'passionate interest groups' (Gee and Hayes, 2011) with like-minded participants sharing knowledge and competence. Such learning is likely to emerge when adolescents "organize themselves in the real word and/or via Internet (or a virtual world) to learn something connected to a shared endeavor, interest, or passion" (Gee and Hayes, 2011: 69). Although everybody is allowed to participate in creating, building, and advancing the shared interest, more shallow participation is also acceptable. Social recognition of participants' accomplishments is determined by the depth of their participation rather than directly reflective of their age or social position. Interest groups have similar kinds of tensions as do other human communities, such as social conflicts, occasional 'flaming,' or 'hazing' of newcomers (Gee and Hayes, 2011: 71).

Although 'geeking out' involves positive developmental possibilities, there are also dangers involved. Middle adolescence is argued to be a period of especially heightened vulnerability to risky behavior (Steinberg) because sensation-seeking is high and self-regulation functions are still immature. In some cases, passions related to use of sociodigital technologies are harmonious in nature (Vallerand et al., 2007) in terms of being well-integrated with other life activities and corresponding to the participants' core values and self-concepts. Observations indicate, however, that many adolescents use sociodigital technologies excessively, find it hard to interrupt their activity, and pursue technology use until late in the night. When passions become obsessive in nature, the participants have a hard time controlling them and there emerge various conflicts with neglected areas of personal, social, and educational activities. In some cases, constant use of the sociodigital technologies becomes deleterious and leads to weakening of real-world networking relations, and, thereby, may hinder psychosocial development (Reich et al., 2012; Smahel et al., 2012). Engagement in using sociodigital technologies appears, consequently, to be a double-edged sword because of the benefit and possible harms of high-intensity participation.

Digital Divide: Creative Participation Gap

The above examination indicated that adolescents' engagement in using sociodigital technologies is likely to be extremely heterogeneous. Most adolescents use digital technologies for entertainment, consuming media, and other shallow purposes rather than engage in building their digital skills, creatively working with media, or adapting sociodigital technologies to support academic pursuits (Bennett et al., 2008; Eynon and Malmberg, 2011; Kennedy et al., 2010). Investigators, moreover, have expressed concerns about an emerging *Creative Participation Gap* (Jenkins et al., 2009), i.e., the unequal access to learning opportunities and formative experiences of mastering creative use sociodigital technologies; this is caused, for example, by social class, gender, or socioeconomic hardship. Adolescents coming from advantaged and disadvantaged homes have unequal opportunities of participating in sophisticated and creative use of sociodigital technologies. Because of socioeconomic and cultural factors, adolescents coming from less privileged families tend to have weaker possibilities for accessing sophisticated sociodigital technologies (programmable computers and relevant applications beyond mere game consoles) that would allow them to go beyond recreational use of sociodigital technologies and creatively engage with them (Ito et al., 2010; Eynon and Malmberg, 2011). Because of cultural stereotypes, the development of sophisticated skills of using sociodigital technologies is likely to be facilitated in the cases of male rather than female adolescents (Barron, 2004).

Adolescents need role models and concrete support for starting to use sociodigital technologies for creative purposes; in this regard, their parents are likely to have a very crucial role. Many adolescents do not have encouragement and parental guidance needed for taking part in pursuing challenging technology-mediated interests (Barron, 2004; Jenkins et al., 2009; Palfrey and Gasser, 2011). Simultaneously, however, an adolescent's own interests, motivation, and sustained efforts play a crucial role affecting the level and impact of parental support. Adolescents who are 'geeking' out may receive their initial inspiration from home, school, or the Internet and, subsequently, distribute their learning across many fields of activity (Barron, 2006). Participants may start sharing their interests or passions with their peers, join Internet-based interest groups, cultivate their interest in entrepreneurial activities (including summer jobs and internships), or utilize Internet-based information sources and network communities. In order to start cultivating sophisticated digital competencies, an adolescent needs to have someone who recognizes his or her interests, and spurs the development of his or her capabilities, in interaction with the adolescent's own agency and effort. From a developmental perspective, social recognition of one's human strengths and contributions to shared efforts is vital (Kindermann, 2007, Larson et al., 2004); digital environments are often very generous in socially recognizing one's achievements and efforts (Shirky, 2010). A special advantage of sociodigital technologies is that passive observation may more or less quickly phase-transform to active engagement in sharing one's experiences and contributions.

An essential aspect of the digital divide is the extent to which sociodigital technologies are used to support academic studies. Although young people may themselves be able to engage in using computers and the Internet to support their social activity, they are much more dependent on parental and teacher guidance when using sociodigital technologies to facilitate academic learning. Heikkilä and Lonka (2006) showed that even many first-year university students appear to have difficulties in self-regulatory skills. They are anxious about not being capable of systematic learning across subject domains beyond their immediate interests. It is crucial to learn to productive use Internet-based knowledge resources as well as various productivity tools, such as text processing, image processing, and presentation software as personal instruments for pursuing various aspects of academic studies. Educational use of sociodigital technologies is still concentrated among students coming from socioeconomically well-to-do families and families with good academic background. Systematic educational support is needed because students coming from disadvantaged homes are not likely to spontaneously cultivate associated skills and competencies.

The investigation of Laursen et al. (2010) indicates that it matters with whom one is 'hanging out.' 'Hanging out' with adolescents oriented toward school and academic activity can provide a protective belt, especially in the case of females, whereas hanging out with adolescents engaged in problem behaviors, such as drinking, is a risk (Kiuru et al., 2009). Networks may lead to either a positive (orientation toward school and academic development) or a negative (exclusion and reification from school) trajectory. Learning is facilitated by hanging out with other adolescents oriented toward studying; this is likely to reduce negative effects of risk behavior. More or less continuous real-time presence of peers when encountering challenges and frustration may make the adolescents overdependent on their peers' support. Adolescents' need, however, to have an ability to invest sustained intellectual efforts in pursuing their school studies, in spite of being temporarily isolated from their peers (Csikszentmihalyi et al., 1996).

Discussion

This article has presented evidence from research literature which indicates that adolescents' ways of using sociodigital technologies are very heterogeneous; although most Western adolescents intensively use sociodigital technologies, only some of them are adept technology users. Thus, we researchers should focus on studying *what* the engagements are of specific subgroups of digital natives rather than consider them as a homogeneous generational population. Social media have affected most strongly the second-generation digital natives born in 1995 or later; these cohorts of adolescents appear to use sociodigital technologies more intensively than earlier ones. Findings of Ito et al. (2010) indicate that most adolescents use sociodigital technologies for friendship-driven practices of 'hanging out,' in terms of being in a constant connection with their extended network of friends by using phone calls, instant messages, text

messages, and social networking services. Such hyperintensive interaction makes social networks a part of adolescents' social operating system (Rainie and Wellman, 2012) and enables them to coregulate their motivation an unforeseen extent. The sociodigital technologies provide affordances for sharing engagement and frustrations and appear to offer significant support to adolescents' activity and development. Adolescents who are 'hanging out' with peers oriented toward school and solving age-relevant developmental challenges have an advantage over those spending time with peers who exhibit various problem behaviors. Although social sharing of one's socioemotional experiences may be developmentally beneficial, adolescents also have to be able to show a certain level of emotional independence that concentrated academic efforts call for (Csikszentmihalyi et al., 1996).

We started this article by discussing the discontinuity between digital natives and digital immigrants, highlighting the distinctive orientation of the young generation to socially share their engagement. Digital adolescents appear to be motivated by activities that provide experiences of autonomy, a sense of competence, and a sense of belonging similar to those that previous adolescents have found outside of digital contexts (Deci and Ryan, 2004). A great deal of present-day creative activity takes place through the Internet, which allows peers to peripherally observe others' activities, to comment on and discuss them as well as to obtain social recognition. Such activity relies on an extended social network and provides multiple possibilities for engaging in more serious 'messing around' with sociodigital technologies, for instance, in making, sharing, and remixing media. Even if only a small percentage of adolescents take very active part in creative activities facilitated by sociodigital technologies, the sociodigital technologies provide affordances for persons to engage in such activities with a very low threshold of effort. Although sociodigital technologies provide all adolescents possibilities to pursue their interests, they are dependent on support of parents, teachers, and other adults (Barron, 2006). Adolescents coming from disadvantaged homes may not have access to sophisticated technology and parental facilitation of creative activity and guidance for learning how to use sociodigital technologies to support school work (Jenkins et al., 2009).

In spite of the radical transformation of adolescents' personal, social, and cultural environments by the sociodigital revolution, there is a lack of systematic longitudinal studies concerning the impact of sociodigital technologies on motivation, learning, and development. In order to overcome such limitations, the present authors' *Mind the Gap* project (www.wiredminds.fi) integrates research on educational psychology, developmental science, technology-mediated learning, and neuroscience to investigate the development of minds of digital natives at multiple levels (personal, family, peer, school class, school, neighborhood). It is possible that the digital natives' extensive technology use, including demands for multitasking and frequent task switching, improves their executive cognitive skills and the related brain functions (cf Patel et al., 2013). However, this issue has not yet been properly studied. In future studies, controlled experimental setups and evolved brain imaging techniques, such as functional magnetic resonance imaging are needed. These studies should be done urgently because it will be soon difficult to find participants for control groups who have still not had extensive exposure to sociodigital technologies.

Socioeconomic Status and Academic Achievement

Abstract

Social economic status (SES), which is often measured as a combination of family income, parental education, and occupational status, has been identified as an important predictor of children's academic success in school. Even before entering school, children's academic performance can to some extent be predicted based on characteristics of their family SES backgrounds. Low-SES families are categorized as having low income which is often associated with the low educational standards of the parents, many of whom live on welfare or minimal wage. Such families are less likely to access social connections and educational resources at home and this may in turn place their children at risk for different academic problems. Initial academic skills seem to correlate with the home environment, where an environment of low literacy and numeracy possibly combined with health problems may negatively affect the development of children's academic skills. The fact that low SES families live together in communities further exacerbates the problem as schools in these communities tend to be under-resourced with high drop-out rates and generally less adequate educational standards. Thus not only do low SES children start school with academic disadvantages, the gap between them and middle SES children widens with time. This article reviews recent research examining the association between SES, child health, family characteristics, school environment, cognitive development, literacy and numeracy achievement, and country characteristics and student achievement. It may shed further light on cognitive development and academic achievement of children with low SES backgrounds and provide grounds for further work on research and practice.

Overview

Two hundred million children or more under the age of 5 years from both developing and developed countries may not fully achieve their developmental and academic potential primarily due to low socioeconomic status (SES) or poverty (Grantham-McGregor et al., 2007). SES factors, which are often measured in terms of family income, parent education, and occupational status, have been identified as an important predictor of children's outcomes. Even before entering formal schooling, children's social cognitive development and academic performance can to some extent be predicted based on characteristics of their family SES backgrounds. The development and achievement gap between children growing up in low SES families and those from well-off families begins in infancy, and widens with age (e.g., Heckman, 2006; Sirin, 2005). There is growing evidence from the US, the UK, and other developed countries that low SES status is correlated with multiple risk factors resulting in inequalities in children's early development and educational attainment. These risk factors are linked with poor child health, poor maternal education, increased maternal stress, poor parent and school support, and inadequate stimulation at home and in school. All these factors further link to poor school readiness skills, including children's physical, social, and emotional well-being, approaches to learning, cognition, and literacy and numeracy acquisition. Not only do low SES children start school with cognitive and academic disadvantages, the gap between them and middle SES widens with time. This article will review recent studies examining the association between SES, child health, family characteristics, home and school environment, cognitive development, literacy and numeracy achievement, and country characteristics during the school year. Understanding of the multiple risk factors can inform priorities for intervention and practices to promote early child development and learning. Broad implications for policies and practices reducing risk factors associated with low SES will therefore be highlighted briefly.

Child Health

Child health has been seen as a fundamental influence on child development and school progress. SES has been shown to be associated with children's health status, with the disparity of health status between low and middle SES children beginning at birth and widening over time (Rothstein, 2004). Frequently, low SES is implicated in multiple diseases including respiratory illnesses that tend to be associated with an increased likelihood of dental caries, higher blood lead levels, iron deficiency, stunting, and sensory impairment (Cohen, 1999). These outcomes may be due to conditions linking with low SES such as inadequate nutrition, exposure to tobacco smoke, failure to get recommended immunizations, and inadequate access to health care. Compared with children from middle SES families, children from low SES families are more likely to be born prematurely, to be low in birth weight, to be born with asphyxia, a birth defect, fetal alcohol syndrome, or AIDS and to have learning-related disabilities because their parents tend to live or work in hazardous and unhealthy environmental conditions, and to smoke, to drink alcohol, to use drugs during pregnancy, and to exercise less (e.g., Bradley and Corwyn, 2002). Such behavioral differences may also influence stress reactions and social affiliations, which are linked with poorer physical and mental health, which may in turn make it harder for low SES parents to provide warm, responsive care or to monitor their children properly.

As low SES children grow up, they generally experience more health problems than do their more affluent counterparts. For example, premature children living in poverty for the first 3 years of life tend to manifest problems in growth, health

 http://dx.doi.org/10.1016/B978-0-08-097086-8.92141-X

status, intelligence, and behavior (Bradley et al., 1994). Moreover, low SES children may suffer from a variety of infections and nutrition-related diseases such as heart and kidney disease, asthma, respiratory infections, ear infections with hearing loss, and a high incidence of injuries. Malnutrition has been found to be associated with poor cognitive development resulting in cognitive delays, low IQ, and problems with motor development (e.g., Anthony et al., 2011). This can in turn cause problems with the ability to concentrate, to process information, and to focus on academic work. Children from low SES families are also less likely to have health insurance and access to health care, thereby leading to a greater risk of illness (Bloom et al., 2006). Health problems put low SES children at a greater risk of school absence than their middle SES peers. Research finds that low SES children are almost three times less likely to have regular school attendance compared to their middle SES peers, and student absences are strongly correlated with poor academic achievement (e.g., Ready, 2010). Because low SES children do not attend school regularly, they receive fewer hours of classroom instruction and consequently perform less well academically.

Family Characteristics

Why is there this correlation between SES and family characteristics with social and academic outcomes? The most important child development and learning takes place in the early years when the family unit provides nurture, support, and stimulation. How effective these are is influenced by the parent characteristics and the resources that families have to devote to child-raising, including their parenting practice and style, and their ability to provide a rich, responsive, and safe learning environment. The widely accepted indicators of SES, namely family income and parental education, are key factors influencing children's academic and social outcomes (Bradley and Corwyn, 2002). For example, cumulated studies (e.g., Riley et al., 2014) have found that economic disadvantage is likely to reduce parents' ability to provide warm and sensitive parenting, and lessen the probability that children will have access to cognitively stimulating materials (e.g., toys, books) and socially enriching experiences (e.g., cultural activities). Findings of these studies provide some support to the family stress model (FSM) and family investment model (FIM). As suggested by the FSM, economic hardship may intensify family stresses and has an adverse effect on parents' emotions, behaviors, and relationships, which in turn negatively impact parenting and parent–child relationships (e.g., Conger et al., 2010). According to the FIM, families with low income tend to put most resources into their basic family needs (e.g., adequate food and housing) and are less likely to make investment in the development of their children (e.g., learning materials and stimulation). Conversely, families with high income are capable of investing more resource in their child development thus leading to the academic and social success of their children (Bradley and Corwyn, 2002). Hence, SES affects child development and academic achievement.

In addition to family income, parent education is another indicator of SES which, too, may affect the child's academic achievement (e.g., Conger et al., 2010; Hampden-Thompson, 2013). For example, less well-educated parents may place a lower value on education than those who have a higher level, therefore investing less resource, both financially and psychologically, in their children's education. Perhaps parents with low level of education tend to be less able to arrange the home environment in a way that is conducive to learning, e.g., ensuring a quiet area for study. Such conditions are likely to affect the child, causing the internalizing of problems such as aggressiveness, opposition, and hyperactivity (Huisman et al., 2010).

Research is suggesting that it is the mother whose educational levels are most influential in low SES families (e.g., Hampden-Thompson, 2013). For example, low maternal education levels are often correlated with low knowledge about child-rearing and child development, leading to less supportive mothering (e.g., Simpkins et al., 2006). Perhaps low academic achievement of the mother results in less well-paid work and so the mother is likely to be overworked in order to help the family income leading to less time to give the child. Frequently the mother does not know what is needed to supply the enrichment opportunities (e.g., providing musical instruments, purchasing books, arranging trips to educational and cultural events) that help cognitive and social development, nor has she the finances to supply these. However, the effects of paternal education levels on fathering have been less examined. One study has found that less-educated fathers tend to have less positive engagement with their children compared to their more educated counterparts (Blair et al., 1994). Others have found paternal education to levels have little influence on such involvement (e.g., Castillo et al., 2011).

When we look at the influence of mothers on girls and fathers on boys, however, the pattern changes. Recent evidence (e.g., Frederickson and Petrides, 2008) has found that gender differences in language and math learning performance increase with lessening levels of maternal education; boys seem to perform less well than girls. However, at the same time, having highly educated mothers may offer more than less educated to the increase in learning performance of boys than girls. Similarly, Cook et al. (1996) suggest that a highly educated father may serve as a role model for boys to identify with academically. Therefore, highly educated fathers also apply greater influence on their boys than on their girls, thus enhancing boys' learning performance. As suggested previously, highly educated parents may be better at providing resources to their children. Possibly boys tend to be more susceptible to disadvantaged environment and could benefit from better socioeconomic environment (e.g., Zambrana et al., 2012). It seems that parental education levels is a protective factor in boys' learning performance and academic achievement.

Family economy and parental education levels may have differential influences on family and child outcomes (Duncan and Magnuson, 2003), and act through different pathways. Whereas family income may have a general influence on children's mental health, parental education levels may affect children's mental health more directly from the effect of parenting. Huisman et al. (2010) have reported that whereas low parental income may influence children's mental problems with both internalized problems such as anxiety and depression and externalized problems such as aggressiveness,

opposition, and hyperactivity, low parental education levels are likely to affect children's internalizing problems only.

Parenting practice also matters. It is known that parents influence their children's literacy skills by reading to them, by using complex language, and by providing appropriate linguistic input and scaffolding. Low SES parents may have difficulties providing this support for various reasons including a lack of skills, lack of time, and lack of awareness of the importance of this sort of parental input (Cabell et al., 2013). As a result, children from low SES backgrounds tend to receive less parental linguistic input and linguistic scaffolding, they fail to receive appropriate linguistic and communicative mediation from their surroundings, they are less actively involved as conversational partners in family get-together, and they engage less in joint book-reading and interactive writing with their parents (e.g., Aram and Levin, 2002). Moreover, low SES parents are less likely to be involved in their children's homework, to participate in school functions, and to volunteer activities relative to their middle SES counterparts. Lack of these practices, which are common in higher SES families, has a negative impact on the development of the skills of the lower SES children. In addition to the parenting practice, parenting style may shape child development and academic attainment. For example, there is evidence that poor parenting manifesting itself in a lack of warmth and involvement, often coupled with harsh and erratic discipline, is associated with aggressiveness, hostility and opposition, and symptoms of anxiety and depression in children (Ma et al., 2012). These parental practices are particularly associated with low SES families and many more low SES children therefore manifest symptoms of psychiatric disturbance and maladaptive social functioning than their middle SES counterparts. These low SES children tend to show internalizing symptoms such as anxiety and depression, and externalizing symptoms such as aggressiveness, opposition, and hyperactivity compared to their middle SES peers (Starfield et al., 2002).

Further evidence of the effect of low SES can be found in the studies of single parent and divorced parents (e.g., Carlson and Corcoran, 2001). The stress of poverty may also increase the possibility of family breakdown, separation, or divorce, which themselves have a detrimental effect on children and their ability to learn. For instance, growing up in single-parent families with low SES has been associated with poor parenting style, thus adversely affecting child cognitive, social, and emotional well-being (East et al., 2006). Compared to two-parent families, children growing up with single-parent families are more likely to have lower scores on cognitive tests and school achievement (Carlson and Corcoran, 2001). Furthermore, single-parent families may experience more stress and maternal depression, three times the level found in two-parent families primarily due to financial strain, poverty, discrimination, and social exclusion. This may, in turn, affect child-rearing behavior and parenting style (Petterson and Albers, 2001). It is possible that stressed and depressed parents are less involved, less sensitive and responsive to their children (e.g., answering child's questions, talking to the child, praising the child), less supportive and warm, and more negative when interacting with their children, leading to increased stress and child abuse. Consequently, living in single-parent families may lead to negative impacts on their child development and academic achievement.

School Environment

The influence of SES on the school environment including child care and preschool may also have an effect on later academic performance. Children from low SES families habitually reside in poor neighborhoods characterized by high levels of unemployment and crime, absence of adult supervision of children, and lack of opportunities for building social networks (e.g., Brooks-Gunn and Duncan, 1997). Living in poor neighborhoods may therefore lead to decreased positive opportunities and is highly correlated with social and emotional problems. At the same time, the majority of schools located in low SES neighborhoods appear to be underresourced and have a school climate less supportive of academic performance as well as of teacher–student relations. Because teachers spend a great portion time dealing with students' discipline problems and welfare, they often have lower involvement in pastoral care and lower expectation of their students' academic attainment. Low SES schools may also have less qualified teachers, which in turn leads to low teacher quality and less rigorous curriculum. The combination of low expectations and less parental involvement in school activities results in a negative school climate and increased risk of school violence, which may weaken children's sense of security and their ability to achieve academic success in schools (Suarez-Orozco et al., 2008).

Cognitive Development

Children's cognitive development and SES are frequently found to be highly correlated (e.g., Duncan et al., 2011), with children from low SES families tending to perform worse on measures of cognitive ability such as attention, working memory, and inhibitory or cognitive control than their more affluent counterparts. Low SES children are also found to be 1.3 times more likely to experience cognitive developmental delays than middle SES children (Brooks-Gunn and Duncan, 1997). The reason advanced for this is again that most low SES children live in a cognitively impoverished environment and receive poor parental nurture. This lack of parental sensitivity and poor cognitive stimulation may have an adverse influence on children's normal brain development, particularly in the prefrontal cortex (PFC) brain region thus posing an increased risk for learning. The PFC is responsible for executive control processes i.e., decision-making, planning, attention, and so forth and has a prolonged period of postnatal development. Research based on electroencephalographic recordings of brain activity (or event-related potentials) are in line with those behavioral studies analyzing attention, inhibitory control, and working memory where SES has consistently been found to correlate with working memory and inhibitory control. A series of research studies conducted by Noble, Farah, and colleagues (e.g., Hackman, et al., 2010; Noble et al., 2007) has shown significant disparities between low SES children and middle SES children in attention, working memory, and inhibitory control all of which are associated with and reflect activities in the PFC region of the brain. In particular, children from low SES families tend to have poor working memory and attention, and less inhibitory control compared to their peers from middle SES families, and these results suggest that low SES children are

more likely to reduce or disrupt their PFC than their middle SES counterparts. Taken together, low SES children may develop different neural systems from middle SES children, affecting the ability to attend and remember relevant information, and filter irrelevant information, and thus leading to cognitive developmental delays and low academic performance.

Literacy Achievement

SES has been shown to be strongly associated with literacy, the building block for all other academic learning: a failure to acquire adequate literacy skills means failure in other academic pursuits. Literacy skills have been recognized as crucial precursors to children's academic achievement throughout their school years. It is important that emergent literacy skills be nurtured and taught before children enter their formal schooling. Research has continually demonstrated that print motivation (i.e., appreciation of stories and books), oral language, vocabulary, concepts of print or print awareness, letter knowledge (i.e., identifying and naming letters), phonological awareness (i.e., identifying and manipulating individual sounds of language), narrative skills (i.e., describing events and retelling stories), shaping and writing skills are the most robust predictors of later reading and writing competence (e.g., Gettinger and Stoiber, 2007).

Although the emergent literacy skills are so important for children's literacy attainment, many children from low SES families may not acquire and develop these essential skills fully, and consequently they enter formal schooling around 2 years behind their peers from middle SES families in literacy development (Clark and Kragler, 2005). Research evidence shows that poor emergent literacy skills are also associated with SES as being linked to poor health, home and school environment, parenting style, and cognitive development (e.g., Anthony et al., 2011). Perhaps not surprisingly, then, low SES children usually lag behind their middle SES counterparts, with delayed development in language skills such as oral language, vocabulary knowledge, letter knowledge, phonological awareness, morphological awareness (i.e., awareness of and access to the meaning of words) (e.g., Schiff and Ravid, 2011). Thus, they often enter school with weakness in these language skills, which has cascading consequences on the development of reading and writing skills. Particularly, children of low SES show weakness in vocabulary, reading accuracy, reading comprehension, spelling, and writing. As a consequence, low SES children with poor emergent literacy skills fall further behind their middle SES peers.

Numeracy Achievement

Like literacy, numeracy is a critical factor in children's academic achievement, and here, too, SES plays a part. Research studies indicate that children's early numeracy skills before and during preschool or kindergarten are significant predictors of mathematics achievement in primary school and beyond (e.g., Jordan and Levine, 2009). The early numeracy skills such as concepts of counting, number competence (e.g., the ability to recognize changes in magnitude), quantity discrimination, numerical relationships (e.g., recognizing which of two numbers is smaller), and number naming have consistently been found to be strong predictors of mathematics achievement (Jordan et al., 2009). These numeracy domains may be important contributors to the development of formal mathematics skills such as addition, subtraction, ordinal sequencing, and mathematical word problems. Prior to starting school, children may use many mathematics concepts and skills in their play and to meet the general demands of daily lives at home.

Children from low SES families may exhibit a low average level of numeracy achievement in preschool or kindergarten, and they continue to trail behind peers from middle SES families throughout schooling. This can be demonstrated by children's use of their fingers to represent and manipulate the quantities represented by number words. In early grades this use of fingers seems to assist children to link with the nonverbal representations and conventional representations with number words and this in turn may lead to mental calculation and fact mastery. However if such finger strategies are prolonged and continuous, the practice may delay development in number competence. It has been found that many low SES children are less likely to use their fingers to represent and manipulate the quantities represented with number words compared to the middle SES children (Jordan and Levine, 2009). Again this may be linked to the quality of parental involvement with the child's very early development in that mothers who have time often spend hours playing counting games on their child's fingers and toes.

Because children from low SES families may have less stimulating home environments and fewer resources for number-related learning, they are less likely to receive support for mathematical development and preparation for school than their middle SES counterparts. Parents of low SES backgrounds may engage in fewer informal mathematics activities and when they do they tend to focus more on simple topics (i.e., counting and shape recognition) than on complex processes (i.e., numerical and geometric reasoning). Further, compared to middle SES parents, low SES parents spend less time teaching number skills to their children and play less informal learning activities such as playing board games with their children because these skills and activities may improve children's understanding of number competence, numerical relationships, and problem-solving skills. Thus, low SES children are more likely to perform less well on tasks related to numerical reasoning and relationships, numerical operations, ordinal sequencing, and mathematics story problems than their middle SES peers. In fact, low SES children have four times the difficulty in solving story problems than the middle SES children (Jordan and Levine, 2009). They are less likely to achieve academic performance equivalent to their middle SES peers, and the gap between low and middle SES children may widen over the course of the school year.

Country Characteristics and Student Achievement

Although evidence has showed that economic inequality widens the literacy and numeracy achievement gap between the privileged and disadvantaged children, countries or territories with greater economic inequality also have lower student achievement overall (Chiu and Khoo, 2005). The Program for

International Student Assessment (PISA), which is to measure the performance of 15-year-olds in reading and mathematics, has generally showed low academic achievement in poor countries with lower gross domestic product per capita. Indeed, the PISA 2012 results show that students in lower SES countries (e.g., Colombia and Peru) tend to have lower academic achievement with reading and math (OECD, 2013). In particular, girls are likely to perform less well on mathematics than boys. Possibly poorer countries have fewer resources at their disposal to invest in education and are likely to allocate their resources and wealth unequally, thus increasing inequality of opportunity and individual outcomes (Chiu and Chow, 2014). In addition, these countries often have fewer public resources (e.g., public libraries and museums) and less teacher quality and education (e.g., qualified teaching staff and certified English teachers). Conversely, students in richer countries may available themselves of these opportunities (e.g., reading more library books) to learn further given that richer countries have more public resources (Chiu and Chow, 2014). As has been discussed, school environment also plays an important role in student achievement. In countries with a high proportion of low SES families and communities, the problem of an inadequate school environment becomes national rather than local with high teacher turnover and low quality, inadequate resources, and increased student dropout rates, all having significant effects on low student performance (e.g., Chiu, 2010). Thus, greater inequality in countries increases the likelihood of lower student achievement.

Conclusion and Implications

This article provides an insight into the multiple risk factors related to SES that influence children's school readiness and in turn impact on children's cognitive, literacy and numeracy development, and their physical well-being and emotional competencies. Risk factors including poor child health, poor maternal education, increased maternal stress, poor parent and school support, and inadequate stimulation in the home and school settings, can negatively affect development and achievement. Understanding the multiple factors is vital when designing effective, evidence-based intervention programs and ameliorative policy actions. Many policies and intervention programs could be used to help children from low SES families overcome the academic disadvantages. For example, policies providing cash supplements and housing assistance might reduce maternal depression and stress. These problems arising from poor health of SES children could be addressed both with food assistance programs designed to improve general nutrition and reduce nutrition-based illnesses and with introducing children's health insurance so that health-related absences could be minimized. Incentives to attract high-performing teachers and principals to schools, and to provide free lunch programs and free textbooks located in low SES communities could be used and money put in to increase family and school resources to enhance the development of low SES children.

Because of the primacy of parenting skills in early childhood development, programs to teach these skills could be devised and implemented. If parents have the ability and time to give their children the same enriched environment as is found in middle SES families, then an improvement in school readiness and academic achievement should result. But before such programs could be implemented low SES families need to have financial assistance so that resources and time become available. Early literacy and numeracy intervention programs are designed to improve the academic achievement of low SES children and help their parents to acquire literacy and numeracy skills contributing to children's learning experience. In addition, such programs may help children connect learning and achievement with positive social interactions and attention with their parents. Furthermore, given strong association between unequal resource distribution, physical resource, and academic achievement, government can provide low SES children with physical resources and improve student learning through equal distribution policies and economic growth. Finally it must be acknowledged that poverty is a world problem of enormous complexity. It affects the academic achievement of the children who are born into it so that they too leave school with inadequate life skills and in turn become low SES parents. It is hoped that this article analyses many of the underlying causes of this lack of achievement and thus suggests areas where intervention could help to break the cycle of poverty.

Summary of the impacts of socioeconomic status

Domains/areas	*Consequences/outcomes*
Health/lifestyles	● Birth defects ● Childhood illnesses ● Inadequate nutrition ● Poor home learning environment
Family characteristics	● Less educated and low income parents ● Single-parent families particularly single mother ● Poor parenting practices and styles ● Poor child cognitive, language and social skills, and emotional well-being
Emotional and behavioral development	● Emotional and behavioral problem ● Mental health problem ● Internalizing and/or externalizing symptoms and behaviors
Cognitive/academic attainment	● Developmental delay ● Grade repetition ● High school dropout ● Learning disability ● Poor working memory and attention ● Less inhibitory control
Home and school environment	● Culturally impoverished home environment ● Lower SES school communities ● Inadequate educational resources ● Poor child development and achievement
Literacy and numeracy achievement	● Poor literacy and numeracy skills for low SES children ● Both benefit from enriched early home and school environment

Abstract

Socioeconomic status is inversely associated with mortality and almost all measures of morbidity in terms of a social gradient that runs from the bottom to the top of society. The social inequalities are highest for drug-related diseases and injuries but are also high for cardiovascular diseases. The most clear-cut reason is social differences in lifestyle, which may explain about half of the health inequalities. The rest of the prevailing health inequalities in affluent societies may be explained by materialistic and psychosocial factors. The high and increasing inequalities in health in the most advanced welfare states are more difficult to explain. Inequalities in health between people in higher and lower social positions show that preventing many diseases and premature deaths is possible. In spite of governmental plans for reducing the divides in most affluent countries, social inequalities in health still seem to increase. A commission under the World Health Organization launched in 2008 a report proposing our leaders and popular movements to start a comprehensive move in policies to reduce social inequalities in the world's health.

In former times, and even today in poor countries, the inverse association between socioeconomic status (SES) and poor health has been obvious to all. Daniel Defoe in his *Journal of the Pleague Year* echoed such sentiments when he wrote "… the misery of that time lay upon the poor who, being infected, had neither food nor physic, neither physician nor apothecary to assist them, or nurse to attend." A change of view started when the Austrian physician Johan Peter Frank published his work in 1790 about the possibilities of reducing misery among poor people by public health measures. In 1848, the German physician and founder of modern pathology, Rudolf Virchow, showed the connection between typhus and poor living conditions in Upper Silesia, concluding with his famous sentence that "medicine is a social science, and politics is nothing else than medicine on a large scale." From the late 1800s, especially British statisticians explored the links between living conditions and health, and were able to demonstrate many new associations between health and SES.

This knowledge was summed up during the Second World War in the political program of the 'welfare state,' which, among others, had an aim to reduce the unfair social inequalities in health. The program was very successful in Northwestern Europe, giving the impression that such inequalities were about to disappear. Therefore, it was a shock when the British 'Black report' from 1980, named after the President of The Royal College of Physicians, Sir Douglas Black, showed that social inequalities in health were increasing in the United Kingdom and in many other Western countries. Since then, research in this field has steadily grown.

In 2005, the World Health Organization (WHO) established the Commission on Social Determinants of Health (2008), led by Sir Michael Marmot, to support countries and global health partners in addressing the social factors leading to ill health and health inequities. Their report concluded that social justice is a matter of life and death. It affects the ways people live, their chances of illness, and their risk of premature death. "We watch in wonder as life expectancy and good health continue to increase in parts of the world and in alarm as they fail to improve in others." Today, social inequalities in health are considered a well-established fact in research, policy, and the wider public.

The Relationship between Social Position and Health

Mortality is the core of health measures. In all affluent countries, it has been shown that mortality is inversely correlated with all available measures of SES – education, income, and occupation. Figure 1 shows the mean remaining years of life for all Canadians aged 25 years across deciles of income with 95% confidence intervals (CIs). The difference was 4.5 (CI 4.2–4.8) years between the lowest and highest deciles for women and 7.4 (CI 7.1–7.7) years for men. These differences are larger in the United States and the United Kingdom; in a study of mortality rates across income deciles in 11 Western countries, Sweden had the smallest difference, and the United States, the largest, with Canada as No. 4 and the United Kingdom as No. 8 (Leigh and Jencks, 2007).

The variance in mortality across SES is relatively high, showing that a lot of factors probably play a role. In a large European study, this was especially high in the low educational groups, largely driven by conditions causing death at younger ages, such as injuries and cancer (van Raalte et al., 2011).

Self-reported health is a good measure of general health. Figure 2 shows the prevalence of poor self-reported health for those with only primary education when the prevalence of those with postsecondary school education is indicated as 1.0 here across educational groups in 11 European countries (Cavelaars et al., 1998). A statistical method is used that adjusts for the size of the different groups, enabling comparability of the columns. Educational differences for this morbidity measure are largest in the Nordic countries and in the Netherlands. The reason may be that the best educated people in these countries enjoyed exceptionally good general health, while those with primary education reported about the same level of general health as in other European countries.

Figure 1 Remaining life expectancy at the age of 25 years after mortality rates in Canada during 1991–2001 by gender and income decile in 1991 with 95% CI. After McIntosh, C.N., Finès, P., Wilkins, R., et al., 2009. Income disparities in health-adjusted life expectancy for Canadian adults, 1991 to 2001. Statistics Canada. Component of Statistics Canada Catalogue No. 82-003-X Health Reports, Ottawa.

Figure 2 The prevalence rate of poor self-reported general health of those with primary education when the prevalence of those with university or other forms of higher education is like 1, expressed as relative index of inequalities (RII: i.e., a measure of inequalities taking into account the different number of people in each category across countries) with 95% CI. After Cavelaars, A.E.J.M., Kunst, A.E., Geurts, J.J.M., et al., 1998. Differences in self reported morbidity by educational level: a comparison of 11 Western European countries. Journal of Epidemiology and Community Health 52, 219–227.

Concerning Figures 1 and 2, it is important to remark that there are stepwise differences in mortality and morbidity across the whole range of social inequalities, such that a social gradient runs from the bottom to the top of society. This pattern is observed among many different diseases. The social inequalities are highest for drug-related diseases and next for injuries, which is understandable, but they are also high for cardiovascular diseases, a fact that is more difficult to understand (see below). Smoking-related cancers follow a steep social gradient, reflecting a high prevalence of smoking among lower SES population groups. Many other cancers demonstrate a similar but less pronounced pattern (Merletti et al., 2011). There are a few exceptions, however; breast cancer, for instance, has a positive association with SES. As age at first pregnancy is a risk factor, and as this age is higher among women with higher SES, this association seems to be explained (Strand et al., 2005). Yet, the problem is more complex because breast cancer incidence is also high among high-SES women without any pregnancy. Similarly, the positive association of testicular cancer with SES remains unexplained.

Age influences these patterns. Social health inequalities are largest for infants, children, and middle-aged people but are also remarkable for old people (Marmot, 2004). The differences are smallest for adolescents (Starfield et al., 2002) or may even be absent (West and Sweeting, 2004). Adolescents are on their way from the social status of parental life, and this may not adequately reflect their own social situation. Moreover, adolescence is a period when health-adverse behaviors are adapted and their adverse health effects become manifest at a later stage of their life course.

Gender is important. Women have all over less social inequalities in health than men (**Figures 1** and **2**). When occupational position is divided into five grades, the top-grade females usually have higher mortality than the second top grade, almost as high as for top-grade men. Some researchers have drawn the conclusion that these women at the top have a life more similar to men than their sisters below.

Lifecourse SES is important when assessing social inequalities in health from fetal life to old age (Graham and Power, 2004). A growing field of research has studied the impact of pregnancy factors on health. Living conditions of mothers are socially patterned, and risks of low birth weight and preterm birth are negatively associated with SES. Both conditions are linked to poor health in adult life (the Forsdahl–Barker hypothesis). Preterm birth is also important for infant health, being a complex cluster of behavioral, psychosocial, and genetic factors as well as contextual characteristics, including access to medical treatment. Many of these factors occur in combination, particularly in those who are socioeconomically disadvantaged or who are members of racial and ethnic minority groups. Childhood SES is especially important because of the strong association with adulthood health (Davey Smith et al., 1998).

Personality characteristics seem to influence both SES and health. In a large French firm, a sample of 14 445 employed persons answered personality tests and were followed up for nearly 13 years (Nabi et al., 2008). The association between risk of death and SES among men was attenuated with 28–29% for 'neurotic hostility,' 13–22% for 'antisocial' personality, and 13–16% for 'CHD-prone' personality (a personality type with increased risk of cardiovascular disease), depending on SES. Personality measures explained some of the mortality gradients across SES for men but had little explanatory power for women. It is not clear if personality represents a predictor or an outcome of social circumstances. A similar study, the British Whitehall study of health in the governmental offices in London, showed that cognitive ability accounted for 17–39% of health inequalities related to SES (Singh-Manoux et al., 2005). In a later US study, the French results of personality profiles and SES were replicated.

Lifestyle, like smoking, food habits, and training, explains a substantial part of the social gradients in health, which was demonstrated by the Whitehall studies (Marmot, 2004). This part is quantified as percentage of variance explained, and different reports observed a range varying between 30% and almost 90% (Stringhini et al., 2010).

Social capital is a concept for an index of amounts of social network, social trust, and norms for reciprocal help in a social group, according to the American sociologist Putnam. Ichiro Kawachi et al. (1997) have shown that social capital of the people in a region is inversely associated with mortality, analyzing state-level data from the United States. Similar associations between health and social capital in regions were later found in several Western countries and in some others, such as Columbia, Brazil, Japan, and South Korea (Murayama et al., 2012). These results have been interpreted as effects of psychosocial factors that influence health-related behavior and other individual-level mechanisms of importance. An example is the social capital factor at the workplace.

Job strain seems to be important for social inequalities in health as extensively shown by Johannes Siegrist and his group. In a study of 47 000 employees, job strain was associated with increased risk factors for cardiovascular disease (Nyberg et al., 2013). More specifically, exposure to an adverse psychosocial environment, defined by high demands and low control and/or by effort–reward imbalance, both more frequent in lower-SES groups, was associated with increased mortality risks (Siegrist and Marmot, 2004). Elevated heart rate and blood pressure and elevated morning secretion of the stress hormone cortisol were found when efforts spent at work were not in balance with rewards in terms of money, promotion prospects, job security, and esteem (Siegrist, 2010).

Area of residence seems to have an independent influence on health (Curtis, 2004). Small-area statistics show that mortality rates are inversely associated with mean income in the neighborhoods. Most of this effect is explained by the fact that people with low individual income are at elevated mortality risk (so-called 'compositional effect'). However, there is some indication that an unfavorable socioeconomic context, like low mean income in an area, exerts an additional influence ('contextual effect').

Social capital in the area, as mentioned above, may have such a contextual effect. Housing qualities are different across social position and very often cluster among people of similar position in separate neighborhoods, thus being both an individual and a contextual factor. Pollution, traffic, and related factors often make poor neighborhoods less healthy. Both the official infrastructure, like schools, sports facilities, parks, and roads, and the availability of private services, like shops for healthy food, are often socially patterned in a similar way.

Time trends are best studied in Europe. Social inequalities in mortality seemed to have reached a peak around 1920, and then decreased toward the 1960s among men and toward the 1970s among women, thereafter increasing again up to now (Mackenbach, 2013). European welfare states were built up after World War II, and one of the important aims was to reduce social inequalities in health. Today, it is clear that all its inhabitants enjoy better health and better economy than before, and yet, it is surprising that health inequalities do not diminish. To the contrary, some of their indicators seem to be still most pronounced in countries with high grants and universal health coverage, as **Figure 2** indicates.

Explanations of Social Inequalities in Health

Johan Mackenbach et al. (2012) has tried to explain the development of social inequalities in health in Western Europe, especially the paradox of the increasing time trend and the high inequalities in the most advanced welfare states. He proposes nine possible explanations:

1. Mathematical artifact
2. A theory of 'fundamental causes'
3. The life course perspective
4. Intragenerational social selection
5. Intergenerational social mobility
6. Psychosocial factors
7. Neomaterialistic explanations
8. Diffusion of innovations
9. Cultural capital

The first three explanations are general theories, which all would require more specific explanations of the 'welfare state paradox' mentioned above. This may be a *mathematical artifact* (1). As the overall levels of poor health decline and mortality differences become smaller, the relative inequalities may turn out to be magnified, or in other words, unlucky outfalls may not alleviate as much as lucky ones over time. A theory of *fundamental causes* (2) is proposed, claiming that fundamental conditions of social stratification ultimately underlay the observed health inequalities, rather than proximal risk factors like smoking, stress, etc. (Phelan et al., 2010). The *life course perspective* (3) maintains that biological programming in fetal and childhood development is the main cause of adult health inequalities, and many still unknown factors may be important in these vulnerable phases of life.

The next two theories focus on how the composition of the social layers is formed by health-related selection.

A theory of *social selection* (4) explains health inequalities by a high intragenerational social mobility in modern societies. It is probable that good health potentials will be associated with upward mobility, and vice versa. Direct social selection effects on mortality have been studied, and this research has demonstrated that intragenerational selection hardly plays any substantial role in explaining subsequent health inequalities (Blane et al., 1999). *Intergenerational social mobility* (5) has been growing in high-income countries in the postwar period (Osler et al., 2005). These slow processes are likely to increase in affluent societies over time, and to be larger in more advanced welfare states. Modern societies have become 'meritocracies' where social position depends on personal talents and efforts, and less on family background. These personal characteristics may partly arise from differences in childhood environments, but may also be due to selection from different social layers.

The two selection theories may explain to some extent how the increasingly smaller groups in the lower social strata tend to consist of people with increasingly smaller resources, thus resulting in a stronger impact of adverse conditions of living on their health. Four theories are focusing on the distribution of specific resources.

Psychosocial factors (6), like control over one's own living conditions, self-esteem, and feelings of success, were proposed to be relevant when Wilkinson and Pickett (2010) demonstrated that inequalities in health were higher in countries with high income differences, e.g., the United States, than in countries with a more equitable income distribution, e.g., Japan. Later, Wilkinson demonstrated that high income differences within distinct countries were associated with a high level of distrust, criminality, child neglect, anxiety, and depression across countries. The association between social capital and mortality is also in line with this theory.

Some years ago, the psychosocial theory was heavily disputed when Lynch et al. (2004) showed, based on more recent data from a higher number of affluent countries, that health inequalities were associated more closely with absolute than with relative income differences. Moreover, Wilkinson's results were restricted to the United States and the United Kingdom. These researchers concluded that health inequalities are more convincingly explained by what they termed a *neomaterialistic* (7) approach where factors like purchase power, housing, holidays, or the quality of infrastructure in different areas of residence matter. The dispute was quite vivid, but not really productive as psychosocial factors, like control and feelings of success, are often based on material conditions, e.g., on a society's willingness to distribute money. Therefore, differences between the psychosocial and the material approach may not be substantial.

Some researchers put the emphasis on *diffusion of innovations* (8), having observed that people in higher positions often tend to be early adapters of new behaviors, who are followed by those in a lower position with temporal delay, as is, for instance, the case with giving up smoking. This theory puts a heavy weight on the results from studies of *cultural capital* (9) and health inequalities. This notion is based on the widely known work of sociologist Pierre Bourdieu who studied social inequalities in consumption behavior. These cultural patterns are explained by differences in attitudes and competencies that are transmitted across generations. Cultural capital may be of growing importance for persons moving up in the social hierarchy, specifically in societies where signs of material prosperity are becoming less important and may exert favorable effects on health behavior.

Mackenbach assumes that 'neomaterialistic' and 'psychosocial' theories explain why social inequalities persist in societies where the majority has access to an 'affluent lifestyle,' while economic inequalities still persist. Yet, the two theories fail to explain the 'welfare state paradox' that inequalities are growing in welfare states. Here, factors like cultural capital and personal characteristics may help explaining the paradox because their effects become stronger under the more equalizing impact of welfare state regimes.

Biological Pathways

Death is a biological and individual occurrence. All nine explanations mentioned above concern phenomena located at the societal as well as the individual level. A crucial challenge for research concerns the question of how conditions associated with people's social position are translated into individual health, resulting ultimately in their death. These processes are still poorly understood, but some possible biological pathways have been elucidated.

Lifestyles, like smoking and diet, have well-known biological effects. But it is more difficult to unravel mechanisms linking psychosocial conditions with physical diseases, such as coronary heart disease with its underlying atherosclerosis. In this regard, Brunner (1997) discussed stress mechanisms as important factors of atherosclerotic development, referring to experiments with monkeys whose levels of the stress hormone cortisol and whose atherosclerotic lesions were increased as a function of disturbed social hierarchies. Social status is associated with stress physiology and health also in humans and other animals, according to Cavigelli and Chaudhry (2012). Psychological stress was shown to be inversely correlated with people's standing in their social hierarchy. Some studies have demonstrated elevated levels of stress hormones like cortisol among people with lower SES, but results are inconclusive. Work stress in terms of effort–reward imbalance was shown to be associated with high morning cortisol level (Siegrist, 2010), and the same holds true for a measure of low

job control (Siegrist and Marmot, 2004). These results can be interpreted as support for the psychosocial explanation of social inequalities (Marmot, 2004).

However, there are additional regulatory systems in the human organism where the central nervous system is intimately linked with endocrine and immune systems to adapt to external demands in differentiated and complex ways (Ulvestad, 2007). Immune function is related to SES in a similar way. The theoretical construct of allostasis (or allostatic load) was introduced to measure accumulated burden on the organism's regulatory systems, which in the long run results in functional loss and structural lesions (McEwen, 2012). These measures have contributed to the understanding of how constantly changing social and environmental factors influence physiological functioning and shape health inequalities, particularly along socioeconomic, gendered, racial, and ethnic lines. The literature demonstrates associations between allostatic load and physical and mental health as well as all-cause mortality (Beckie, 2012).

Nancy Krieger (2013) maintains that these relationships between social and bodily processes may change over time. She therefore suggests that diseases and their biomarkers may be thought of as *embodied histories*, that is, as emerging embodied phenotypes rather than as resulting from 'inborn biology.'

Political Implications and Conclusion

Reducing social equities in health has come to the political agenda in most Western countries. An example is governmental support to the Acheson Report (1998) in the United Kingdom. This report gave 39 principal recommendations in order to reduce poverty in women of childbearing age, pregnant women, young children, and older people. Recommendations included a reduction of income inequalities and an improvement of living standards of households among recipients of social security benefits. Moreover, deprived conditions of ethnic minority groups; unemployed, elderly, and disabled people; and families with children should be improved, and benefit levels and real living standards should be increased. Other recommendations concerned improvements of material conditions in schools, housing, environment, transport, and diet. The Labor government of 1997 tried to set much of this plan into policy but only some of the main aims were met (Mackenbach, 2010). Three main reasons of the failure to meet these goals were discussed. First, some entry points were not relevant for changing health and life expectancy; second, the proposed strategy was not able to use effective policies; and third, the strategy was not delivered at a large scale with sufficient impact.

Similar policy measures were proposed in the US context (Adler and Newman, 2002). An overview of distinct governmental programs in four countries, the United Kingdom, Sweden, Denmark, and Norway, showed that all strategies dealt with the challenge of increasing social inequalities in health, the English and Swedish strategies more so than the other ones, but there was no specific Nordic model in this field of welfare state politics (Valgårda, 2001).

Economic globalization may widen the gap between what we know about social health inequalities and health policy efforts in affluent societies (Siegrist, 2008). It is hoped that rapidly developing countries can learn from Western societies how important it is to identify, monitor, explain, and reduce social inequalities in health. Clearly, given the scope of this problem and the role of sociocultural differences across the world, substantial challenges remain for science as well as for policy.

Despite these challenges, the Commission on Social Determinants of Health (2008) of WHO demonstrated some promising ways of tackling inequalities in health. The commission stressed the importance of 'health in all' policies, emphasizing that action on the social determinants of health is needed, across the life course and in the wider social and economic spheres.

This article is a revision of the previous edition article by P.M. Lantz, volume 21, pp. 14558–14562, © 2001, Elsevier Ltd.

Abstract

There is a vast amount of evidence across countries that the use of health care services (including hospitalizations, physician services, and clinical preventive services) is positively associated with income, education, and other markers of socioeconomic position. In some analyses, lower socioeconomic status (SES) is associated with greater physician and hospital use, although it appears that these findings are primarily driven by higher rates of poor health status or medical need in socioeconomically disadvantaged populations. Three general sets of explanations have been investigated to explain SES differences in health care use: financial access or affordability differences (e.g., the poor use fewer services because they have fewer financial means); knowledge, attitudinal, and cultural differences in seeking care (e.g., the poor use fewer services because they value and/or understand the benefits of health care less than other people); and health care system factors (e.g., the poor use fewer services because of ways in which the health care system is organized). The empirical evidence from a number of countries suggests that health care system variables, especially nonfinancial components of access, offer the greatest explanatory power regarding SES differences in utilization. The policy implications of such findings are important, for they suggest that providing universal coverage or offering free health services to the poor is not a panacea for reducing social inequalities in health care utilization. Research across countries also suggests that, although SES differences in the use of health care services may contribute to some portion of observed SES disparities in health status, the contribution here is likely to be small. Social inequalities in health status are driven by myriad factors other than access to and use of personal health services.

Socioeconomic Status and Health Care

Although many factors determine the availability and use of health care, there is substantial evidence across countries that markers of socioeconomic status (SES), including income, education, and occupational status, are significantly associated with health care utilization. This includes health insurance coverage and the use of personal health services such as visits to primary care providers and specialists, hospitalizations, dental care, vision care, mental health services, prescription drug use, and home health care. Although there is ample evidence that people of higher socioeconomic position use more health care services and tend to receive higher quality care, the reasons behind these disparities are not fully understood. Later on, the relationship between SES and health services utilization is described, and explanations for this relationship are summarized.

The Relationship between SES and Health Care Utilization

Numerous studies have found a positive relationship between SES and most types of health services utilization, measured by whether or not a service type was used in the past year, or as the mean number of encounters/visits for the service during a specified time period (National Center for Health Statistics, 2012; Ross et al., 2006). Although there are some exceptions to these general findings, the bulk of the empirical findings to date suggests that the association is positive; that is, higher SES is associated with a higher rate of health care utilization (see **Table 1** for some examples from the United States). Exceptions occur in cases when certain types of health care utilization indicate poor access to health services that are considered essential to maintain health and well-being. An example of this is higher rates of emergency department (ED) use for lower socioeconomic levels, signaling potential barriers to accessing primary and specialty care services. Higher SES is also associated with lower rates of untreated disease and unmet medical needs. That SES has a positive impact on health care use has been observed for both men and women, and for children and adults.

While the association between SES and health care utilization is positive and graded in most studies, other patterns have been documented as well. An inverse association between SES and use of physician services was noted in Canada, along with the hypothesis that excess use by those of lower income and education levels is attributable to SES differences in health status (Kephart et al., 1998). Among children in five Nordic countries, few differences were found in the use of physician services for different socioeconomic groups (Halldorsson et al., 2002). In the United States, those without health insurance, those living in low-income areas, and racial/ethnic minorities are significantly more likely to receive potentially avoidable hospitalizations and medical procedures (Pappas et al., 1997; Blustein, 1998). In summary, people from lower economic and educational strata tend to have fewer physician visits for both primary and specialty care and to use fewer mental health, dental, vision, and preventive services. They also are less likely to have a usual source of care and have significantly higher rates of unmet health needs. In some analyses, lower SES is associated with greater physician and hospital use (especially for avoidable causes of injury or illness), although it appears that these findings are primarily driven by higher rates of poor health status or medical needs in disadvantaged populations.

Table 1 Health care utilization by poverty status for selected measures, United States, 2007–2010

Health service	*Poor*	*Near poor*	*Middle income*	*High income*
No health insurance				
Children (<18 years)	22.0%	22.8%	8.6%	4.2%
Adults (18–64 years)	44.1%	35.3%	13.8%	6.1%
No usual source of care				
Children (<18 years)	8.3%	7.5%	4.7%	2.1%
Adults (18–64 years)	33.8%	30.5%	20.5%	10.8%
Did not get care due to cost				
Adults (18–64 years)	23.4%	24.0%	15.2%	6.8%
Use of pap smears				
Women (>18 years)	65.1%	64.3%	71.3%	83.1%
Dental visit in past 12 months				
Adults (18–64 years)	41.0%	44.1%	59.6%	77.1%
ED visit in past 12 months				
Adults (18–64 years)	30.6%	25.6%	20.4%	17.0%
Persons with self-assessed fair or poor health				
All ages	20.9%	15.2%	8.3%	4.3%

SES and its proxies are not the only factors related to health care use. Utilization is also patterned by gender, geography, age, culture, and other factors. While it is difficult to sort out the independent effects of SES and race/ethnicity on health care, it appears that minority status has an important independent effect. In the United States, certain racial and ethnic minorities (most notably, African-Americans, Native Americans, and Hispanics) have been found to have lower rates of utilization in general, to receive less aggressive care for certain diseases, and to report less satisfaction with and more experiences with discrimination regarding, health care (Institute of Medicine, 2002; Fiscella et al., 2000). Even so, SES appears to be a major social predictor of health care use. The relationship is strong across different types of health services and is robust across a variety of study designs from a number of different countries.

Explanations for the Relationship between SES and Health Care Utilization

While the evidence for a relationship between SES and health care use is strong and compelling, there are many methodological challenges in measuring this association and its causes (Brown et al., 1998). First, the relationship is confounded by health status, which is related to both SES and the need for services. Thus, it is important to measure health services utilization within the context of medical need. Second, it is difficult to have all necessary variables in a single population-based data set, including valid and reliable measures of SES, health insurance, medical need, and other confounding factors. Third, there are many different types of health services, and relationships are not uniform in magnitude or patterns across these different types. Fourth, simple measures of utilization do not provide a very deep understanding of differences that may exist in terms of the quality, content, or continuity of care.

Despite the methodological challenges for this type of research, several factors have been investigated to explain why people of lower SES generally use fewer health services than those of higher social position and why their level of use does not appear to match their need. Dutton (1978) reported that explanations for this phenomenon generally fall into three categories: explanations that focus on financial access or affordability differences (e.g., the poor use fewer services because they have fewer financial means); explanations that focus on knowledge and attitudinal differences regarding care seeking (e.g., the poor use fewer services because they value and/or understand the benefits of health care less than other people); and explanations that focus on health care system factors (e.g., the poor use fewer services because of how the health care system is organized or responds to them). This set of explanations still reflects the primary reasons offered for the strong association between SES and health care utilization.

Financial or Affordability Explanations

Since being uninsured is strongly correlated with income and education, it is often assumed that the strong relationship between SES and health care use operates primarily through the more proximate variable of health insurance. People with health insurance generally have a usual source of care, a measure that serves as a proxy for access to stable and accessible primary and preventive health services (see **Table 2**). Those who are privately insured, who generally are employed in firms that offer health coverage as a benefit of employment, have greater access to health services and in general enjoy better health than individuals who are uninsured or are insured by Medicaid, the US health insurance program for certain categories of low-income and disabled individuals. Expanding Medicaid in certain US states has been associated with better access and greater use of health care services for low-income individuals (Sommers et al., 2012; Baicker et al., 2013). Major health reform initiatives in the United States through the Patient Protection and Affordable Care Act will result in millions of uninsured individuals obtaining health coverage through subsidized private health insurance markets for

Table 2 Health care utilization by insurance status and type of coverage for selected measures, United States, 2009–2010

Health service	*Private insurance*	*Medicaid*	*Uninsured*
No usual source of care			
Children (<18 years)	2.6%	3.4%	28.8%
Adults (18–64 years)	10.5%	12.5%	50.6%
ED visit in past 12 months			
Adults (18–64 years)	17.4%	40.2%	21.3%
Pap smear			
Women (>18 years)	84.2%	78.0%	61.9%

Reproduced from Special Feature on Socioeconomic Status and Health, 2012. Hyattsville, MD.

low- and middle-income individuals (known as health insurance exchanges) or state Medicaid expansions that enable more of the country's poor and near-poor to qualify for coverage (Rosenbaum, 2011). These policy changes recognize the strong relationship between coverage and access to health care and the effects of lack of health insurance coverage on health. They also hold promise for increasing the share of Americans who have a usual source of care, which can also yield benefits in terms of strengthening primary care and preventive services and decreasing use of unnecessary and costly care (Lillie-Blanton and Hoffman, 2005; Fiscella, 2011).

Nevertheless, even among people with health insurance, lower levels of income and education are associated with lower overall health care use (Collins et al., 2012). Although access to health care is often equated with financial access, access is in fact multidimensional, and other aspects of access (such as the availability, convenience, and acceptability of providers and services) are of equal importance (Gold, 1998). Thus, SES differences in health care use are not fully explained by economic or financial factors.

Knowledge, Attitudinal, and Cultural Explanations

Lower use of health services among disadvantaged populations may be explained in part by chronic stressors and challenges associated with poverty (Adler and Newman, 2002). These stresses may result in a lack of attention to health and underuse of health care services generally or lower use of care-seeking behaviors for specific symptoms or conditions. Increasingly, research on health services utilization and SES has focused on developing an understanding of patient preferences and individual health needs as they relate to health care. Patient centeredness has emerged as a core value of high-quality health care delivery that recognizes the need to respect individuals and families as they make health care decisions (Institute of Medicine, 2001). Patients' knowledge of the importance of health services is associated with racial and ethnic concordance between the patient and health care provider, the patient's preferred language, the effects of chronic health conditions or disabilities on the patient's health care experiences, and a health care provider's ability to provide health care that is culturally and linguistically appropriate (Agency for Healthcare Research and Quality, 2012a). African-Americans, Hispanics/Latinos, Asians, and other groups exhibit different use patterns that may reflect, in part, different knowledge, cultural values, and preferences that may also vary by SES. Dissatisfaction with health care, lower rates of compliance, poorer understanding of health conditions, and lower self-rated health status are better explained by health system-level deficiencies rather than previous constructs related to a culture of poverty (Niewczyk and Lwebuga-Mukasa, 2008; Baker and Newsom, 2003).

Health Care System Explanations

Measures of health care quality are lowest for poor and low-income individuals. Empirical evidence from a number of countries suggests that health care system factors, especially nonfinancial components of access, offer the greatest explanatory power regarding SES differences in utilization. Research has shown that SES differences in health care utilization are driven much more by structural elements of the health care system than by individual factors such as health insurance or other financial variables (Rosenbach et al., 1999). These system-level factors include cultural deterrents to care, the unwieldy nature of large medical bureaucracies, fragmentation in care, racism, and other forms of provider bias, transportation barriers, and nonfinancial dimensions of access.

Not only is SES related to health care utilization, it is also related to health care quality (Fiscella et al., 2000). In 2001, the Institute of Medicine of the US National Academies of Sciences defined high-quality health care as care that is safe, timely, effective, efficient, equitable, and patient centered. This work set the stage for further studies to describe racial, ethnic, and linguistic disparities in health care. Despite an emphasis on high-quality, equitable care, disparities associated with race, ethnicity, and income level persist, with key measures of quality showing little or no improvement over the last decade (Agency for Healthcare Research and Quality, 2012b). On many measures of quality, African-Americans and Hispanics in the United States continue to receive worse care compared to whites. Quality of care measures is lowest for poor and low-income individuals, as are most access to care measures. Even individuals with better access may not receive the full complement of services that are considered by experts to be within the recommended standard of care. Despite spending more than any other country on health care, the average adult in the United States receives only about 55% of recommended services and children receive even less (McGlynn et al., 2003; Mangione-Smith et al., 2007).

It is important to view these quality deficiencies within the broader context or system of how health care services are

organized, delivered, and financed. Payments for health services in the United States have traditionally been linked to volume or fee-for-service type arrangements, which leave little incentive for health professionals to improve the quality of care they provide. Efforts to monitor quality have also been hampered by limitations in data collection and analysis, a situation that may improve with the broad implementation of health information technology and electronic health records. Yet even with these advances, the policy implications suggest that providing universal coverage or offering free health services to the poor is not a panacea for reducing social inequalities in health care utilization. Changes to ways that health care is organized and delivered may prove critical to reducing health care disparities in health services utilization.

The Role of Health Care in Explaining SES Disparities in Health Status

There are many explanations for the strong relationship between SES and health status, as outlined in the accompanying article on this topic (*see* Socioeconomic Status and Health). This includes explanations that focus on different material resources, of which health care is viewed as an important type (MacIntyre, 1997). Research from a number of countries suggests that, for specific health conditions, the receipt of clinical preventive services and/or timely therapeutic care plays an important role in health outcomes, and thus may account for some portion of socioeconomic disparities in health status (Lantz et al., 1997). Therefore, it has been argued that efforts to increase the use of health services among the socioeconomically disadvantaged, primarily by reducing financial barriers to health care or health insurance, have great potential for reducing socioeconomic disparities in health status (Sommers et al., 2012; Andrulis, 1998).

Research at the end of the twentieth century, however, also suggests that the contribution of SES differences in health care use to overall SES disparities in health status is likely to be small (Adler et al., 1993; MacIntyre, 1997; Baicker et al., 2013). Evidence for this comes from a variety of sources, including, as described above, countries with universal health insurance. For example, the Black report demonstrated that socioeconomic inequalities in mortality in England and Wales increased rather than attenuated in the decades after the British National Health Services was established (Gray, 1982). It has also been shown that, in developed countries, there is no relationship between health indicators (such as life expectancy) and the proportion of economic resources spent on health care (Roberts and House, 2000). The United States, Canada, and Great Britain are all experiencing increasing disparities in life expectancy between higher- and lower income individuals as well as higher- and lower educated people, despite the availability of universal health coverage in the latter two countries (Congressional Budget Office, 2008). While it is important not to overgeneralize from these ecological studies, a wide variety of research strongly suggests that differential access to and use of personal health services is but one of myriad factors contributing to social inequalities in health status (Roberts and House, 2000; MacIntyre, 1997).

With respect to developing countries, it is clear that economic development, growth in formal education, and public health measures such as clean water and basic nutrition are of greater significance to population health than the delivery of health care. While the importance of personal health services (such as immunizations, HIV medications, or oral rehydration therapy) in less-developed countries should not be underestimated, broad public health and economic development advances are believed to afford the most potential for making significant improvements in health.

This is not to suggest that health care has no impact on individual health or social disparities in health status. There are indeed some diseases and conditions for which health services can significantly reduce morbidity and mortality, and improve physical functioning and quality of life, as demonstrated in clinical trials and other types of studies (Starfield, 2012; Kates, 2011; Andrulis, 1998). The bulk of the knowledge generated to date, however, suggests that while reducing SES disparities in health care may help to reduce socioeconomic and racial disparities for some specific diseases or health issues, significant inequalities in health status would be likely to remain. Environmental, community, socioeconomic, and psychosocial exposures to both health risks and health-promoting resources would still exist, creating disparities in the incidence and prevalence of a number of health problems. Furthermore, many health conditions and problems are not amenable to medical interventions or to prevention practices delivered through health care providers.

It is also important to emphasize that socioeconomic disparities in health care are not immutable (Fiscella et al., 2000). Thus, many researchers, clinicians, advocates, and policymakers alike believe that efforts should continue to be made across and within countries to reduce SES differentials in health care access and utilization by focusing on the financial, attitudinal, and most importantly, health system barriers that contribute to these significant disparities. The policy goal should be a health care delivery system in which all dimensions of access and the content and quality of care delivered are the same across social strata.

Socioeconomic Status and Social-Emotional Development of Children from Birth to 36 Months of Age: A Systematic Narrative Review

Beverly Gaudet, Faculty of Nursing, University of New Brunswick, Fredericton, NB, Canada
Nicole Letourneau, Faculties of Nursing and Medicine (Pediatrics and Psychiatry), University of Calgary, AB, Canada

Abstract

While it is widely accepted that socioeconomic status (SES) has an impact on the development of children, it is critical that we define SES beyond a narrow focus on income. It is also imperative to understand its impact on a specific dimension of early childhood development, socioemotional development, beginning at an early age. Thus, the objective of this article was to conduct a systematic narrative review to examine the relationship between broader conceptions of SES and young children's social-emotional development. The findings suggest that SES begins to have a negative impact on social-emotional development early in life.

Childhood development and socioeconomic status (SES) are both identified by the Public Health Agency of Canada (2009) to be determinants of health that, individually or in combination, influence the health of individuals. Low SES is likely to negatively affect an individual's future prospects, opportunities, and quality of life (Hayes, 2008; Public Health Agency of Canada, 2009). According to Bradley and Corwyn (2002), the link between SES and social-emotional development in children has not been identified as consistently as the connection between SES and cognitive development in children, particularly in language and executive functions, which emerge in preschool and older childhood (Hackman and Farah, 2009). However, the period from birth to age of 3 years has been described as critical for physical, social-emotional, and cognitive development over the life span due to heightened sensitivity of the brain and other developing organ systems to environmental influences. Further, social-emotional development in infancy, specifically associated with brain development and mental health over the life span, may be the most important feature of development in early childhood (Center on the Developing Child at Harvard University, 2010; Siddiqi et al., 2007).

Cognitive development may in fact depend on social-emotional development, as managing emotions may be necessary for learning difficult tasks such as counting or reading (National Scientific Council on the Developing Child, 2011). In this way, the foundations of developmental health in all domains are linked to emotional well-being and have an impact on a child's future ability to maintain a job and work well with others and for practicing effective citizenship and contribute to a community (National Scientific Council on the Developing Child). Taken together, the sensitivity of young children's development to environmental influences is particularly worrisome when their families struggle with low SES. The early social environment is critical in influencing the formation of neural networks that regulate a child's social-emotional development, including response to stress and capacity for self-control (DiPietro, 2000; Hertzman, 1999; Irwin et al., 2007; Leventhal and Brooks-Gunn, 2000; McDonald, 2008; National Scientific Council on the Developing Child, 2011; Ridge, 2002).

Understanding the effects of SES on young children's social-emotional development has been complicated by a variety of factors, including (1) inconsistent measurement of SES across studies; (2) use of single indicators of SES (e.g., employment) rather than broader conceptions of SES; (3) inclusion of SES as a control variable rather than actually examining the impact of SES on social-emotional development; (4) low SES is an inclusion criteria for studies examining other risk factors such as maternal depression, maternal drug use, and quality of the home environment, so comparisons among SES groups are precluded; (5) little research has isolated SES as a specific indicator of social-emotional development in infants and children; and finally, (6) SES is often related to outcomes in older children such as those of school age. As a result, the link between SES and social-emotional development in young children remains unclear.

To more accurately and effectively affect policy and intervention programs, it is important to isolate at what point SES begins to impact social-emotional development in children. Poverty in early childhood may be more detrimental to long-term behavioral and achievement outcomes than if poverty is experienced during middle-childhood or adolescence (Duncan and Brooks-Gunn, 2000). In spite of the recognition that the first 3 years of life represent a period of particularly rapid development of cortical structure and function (DiPietro, 2000), very little work has rigorously explored the influence of poverty, let alone broader conceptions such as SES, on young children's social-emotional development. Thus, a review was undertaken to examine the influence of SES on young children's (from birth to 36 months of age) social-emotional development.

What Is Social-Emotional Development in Young Children? Why Is It Important?

Shonkoff and Phillips (2000) describe social-emotional development as the capacity to identify one's own feelings and the ability to constructively manage strong emotions. A child's ability to self-regulate in early development is thus interconnected with the child's relations with others.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.23053-5

Social-emotional development also represents the capacity for children to develop and learn from relationships. For example, a toddler learns that the people he or she depends on for comfort will help when she or he is distressed; therefore, the toddler will be more likely to approach others with trust and expectations of empathy.

Social-emotional development is positively correlated with the growth of new skills and abilities in young children; thus, when children are unable to manage their feelings, their thinking can be impaired (National Scientific Council on the Developing Child, 2011). Birth to age of 3 years is a time to develop relationships, regulate and express emotions, form close and secure interpersonal relationships, and explore the environment and learn – all in the context of family, community, and cultural norms for young children (Fitzgerald et al., 2011; Siddiqi et al., 2007). In summary, infant mental health is directly related to healthy social and emotional development (DiPietro, 2000), and early social-emotional development provides the foundation for psychosocial well-being and mental health over the life span (Shonkoff and Phillips, 2000).

Social-emotional problems in infancy and young childhood reduce older children's capacity to forge healthy relationships with peers and adults, which then impedes fundamental cognitive, linguistic, and self-regulating abilities. In this way, early challenges with social-emotional development predict more serious mental health issues in later childhood, adolescence, and even adulthood (Bricker et al., 2004); as a result, by school age, many opportunities for intervention will have passed. In order to more accurately inform social policy and programs, it is critical to identify at what age low SES begins to have a negative impact on children's social-emotional development. Knitzer (2008) argues that early detection and treatment will prevent children and adolescents from becoming frequent users of the health-care system, thus reducing health-care spending over the long term. Bricker et al. (2004) posit that treating young children is less expensive and perhaps more effective than postponing intervention until middle-childhood or adolescence. Indeed, treatment becomes less effective when social-emotional problems become deeper rooted over time.

How Do We Define SES?

Poverty as a measure of SES has been criticized for its narrow focus on income (Bradley and Corwyn, 2002; Hackman and Farah, 2008; U.S. Department of Health and Human Services, 2000). SES includes not only income but also other socio-demographic variables that more fully characterize the social and economic environment for children. Moreover, a narrow focus on poverty as a measure of SES necessarily limits interventions to income support and precludes consideration of broader factors that could become the focus for interventions with low-SES families. As a result, increasingly SES is considered more broadly and includes not only income but also parental education, marital status, neighborhood characteristics, and child-care quality (Bradley and Corwyn, 2002). Much of the research done to date refers only to income (from all sources, including government subsidy) or income-to-needs ratio as a measure of SES. Stepping beyond income as the focus of SES gives a clearer illustration of someone's financial situation, as SES should include nonmaterial resources gained through social connections such as education (Bradley and Corwyn, 2002). Composite definitions of SES (using multiple indicators of SES) increase the validity and generalizability of findings. Thus, for the purposes of this article, rather than using a single indicator of SES such as income, SES was conceptualized more broadly. SES was defined using a composite measure of at least two of the following: parental education level, parental marital status, parental employment status, parental occupation prestige, and household income and eligibility for subsidy (Ensminger and Fotherill, 2003).

Theoretical Underpinnings of Review

Two theories guide the focus of this article. First, Erikson's theory of psychosocial development (1963) is based on qualities of the social environment that are required to meet a child's basic needs. Between birth and 1 year of age, children must establish trusting relationships with caregivers. If basic needs (e.g., for nourishment and comfort) are not met, then the young child learns to mistrust others with implications for mental health over the life span. Between the age of 24 and 36 months, young children must establish their autonomy in relationships with others. Children need to develop a sense of personal control over physical skills and gain a sense of independence; failure to achieve these skills results in feelings of shame and doubt with additional mental health implications over the life span. Second, Bronfenbrenner's ecological model of human development (1994) emphasizes the entire ecological system to understand human development. Early and throughout life, human development occurs through a series of complex reciprocal interactions between the individual and his or her immediate environment. Infants do not experience low SES directly, but only through their interactions with caregivers. Low-SES caregivers may be strained, stressed, and distressed in coping with the low-SES conditions, which may affect interactions with their infant. Further, young children may not receive adequate nutrition or stable housing from their low-SES caregivers, who are limited in what they can provide. The family environment provides children's first experiences and human contact; thus, families are most often the ones to mediate a child's contact with their larger environment (Kohen et al., 2002). Thus, Bronfenbrenner requires that we take a broader view of influences on children's development.

In summary, the purpose of this article was to conduct a systematic narrative review of the relationship between composite measures of SES and social-emotional development in children between ages of 0 to 36 months. The secondary purpose was to examine the influence of moderating variables.

Methods

Due to the complexity of issues surrounding the impact of SES on socioemotional development, a systematic narrative review was conducted to examine the relationship between SES and social-emotional development in young children. A systematic narrative review adheres to a set of scientific methods to prevent the limitations associated with bias by attempting to

assess and synthesize all relevant evidence to answer a clear, targeted question (Mays et al., 2005). Systematic narrative reviews seek to explore the diversity and variety of literature to be more comprehensive in identifying the strengths of evidence. The intent is to lend support to the research question or identify areas of uncertainty or gaps where more research is needed (Mays et al., 2005) in order to inform research, practice, and policy.

Search Strategy

Papers discussing the impact of SES on social-emotional development were searched electronically through CINAHL, MEDLINE, and PsycINFO – the databases most likely to yield relevant research. The following keywords were used: SES, socioeconomic factors, social class, family background, career mobility, poverty, employment, occupation prestige, household income, parental characteristics, parental education, marital status, emotional development, social development, social-emotional development, internalizing behaviors, depression, anxiety, infant development, and child development. Consistent with the characteristics of exemplary literature reviews, the ancestry approach was used to scan the reference lists from the retrieved articles to identify other relevant citations (Jackson, 1980).

Criteria

Inclusion of studies was limited to those published during the last 10 years (2002–12) to reflect a clearer, more contemporary understanding of SES and its associated implications. The search was further limited by including only those (1) written in English, (2) on human subjects, (3) on children 0–36 months old, (4) on children born healthy at full term, (5) on children with no organic health conditions or developmental disorders (e.g., autism, attention deficit hyperactivity disorder), and (6) on healthy parents. Children and parents with disorders (e.g., mental illness or developmental problems) were excluded from the search, as the review sought to examine social risks, not physical or biological risks. The final set of papers was achieved by consensus of the two authors. **Figure 1** summarizes the review process.

Results

A total of four studies were included; all were longitudinal birth cohort studies. The studies were conducted in Australia ($n = 1$), the United Kingdom ($n = 2$), and the United States ($n = 1$). The total sample size was $n = 31\ 381$. The sample was racially diverse; Flouri et al. (2010) described their sample as representative of families living in poverty in Northern Ireland, Scotland and Wales, and areas in England with populations of high ethnic minorities. The sample in the study done by Kiernan and Huerta (2008) came from areas with high proportions of ethnic minorities in the UK. Nicholson et al. (2012) described their samples as representative of Australia's population, including children of highly educated parents

Figure 1 Search Results

overrepresented by 10%, and children who had single parents, were non-English speaking, and were living in rental properties were slightly underrepresented. Zilanawala and Pilkauskas's (2012) study contained an over sample of nonmarital births in large U.S. cities with populations over 200 000. As a result, their sample represented families who were more likely to be with low income, with absent fathers, and had mothers with a lower level of education than a sample representative of the nation. About one-third of mothers were black (35%), just under one-third of the sample were Hispanic mothers, and approximately one-quarter of the sample were white mothers.

The measurement of SES within these four studies varied. Flouri et al. (2010) used two composite measures of SES, including the Index of Multiple Deprivation (IMD) and family SES. The IMD assessed income deprivation, employment deprivation, health deprivation and disability, education, skills, and training deprivation, barriers to housing and services, living arrangements, and crime. The family SES measures examined overcrowding, lack of home ownership, receipt of income support, income poverty (below the poverty line), and lack of access to a car or van. Kiernan and Huerta (2008) used the measures of income poverty, financial difficulties, and housing tenure, i.e., owning or renting a home versus living in publicly subsidized housing. Nicholson et al. (2012) defined SES by the combination of parental income, education, and occupational prestige. Zilanawala and Pilkauskas (2012) defined SES as ability to pay utilities, food, and medical bills and housing instability. They also included a second measure of SES that included the household's income-to-needs ratio, education status, and employment status.

Of the four studies reviewed, all found a significant relationship between SES and internalizing behaviors in children from birth to 36 months of age. **Table 1** summarizes the findings of the studies. Two of the four studies found evidence

Table 1 Overview of search results

Author(s)/country	*Purpose*	*Design*	*Key measures*	*Findings and moderation*
Flouri et al. (2010) Children of 3 years of age in nine strata in the UK including areas with high ethnic minority populations as well as areas of child poverty	To determine the area and family contextual risk factors on young children's psychopathology	Longitudinal cohort study	• Area SES: income, employment, health, education, barriers to housing/services, living environment, and crime • Family SES: overcrowding, lack of home ownership, receipt of income support, income poverty, lack of access to a car • Emotional symptoms, peer problems, prosocial behavior *Child-level covariates*: age, sex, developmental milestones, and temperament (9 months)	• Family SES predicted prosocial behavior ($b = 0.043$, SE $= 0.021$) and peer problems ($b = 0.050$, SE $= 0.017$) • No moderation of relationship between SES and social-emotional development examined; however, the relationship between family SES and psychopathology more generally was moderated by child characteristics (e.g., age, sex) and family adversity
Kiernan, K.E. and Huerta, M.C. (2008) Children of 3 years of age from four countries in the UK, living in areas with high rates of child poverty and in areas with high proportions of ethnic minorities	To examine the extent to which SES in infancy and mother's mental health are associated with children's emotional development at 3 years of age	Longitudinal cohort study	• Economic deprivation: Income, financial difficulty, and housing tenure • Background controls: Marital status, maternal education level, maternal employment status at age of 9 months • Internalizing problems	• Findings revealed that children living in low-SES families have a higher risk of experiencing internalizing behavioral problems ($d = 0.18$, $p < .001$) • Children whose mothers are depressed tend to experience more internalizing behaviors ($d = 0.13$, $p < .001$). Total direct ($d = 0.10$, $p < .001$) and indirect ($d = 0.03$, $p < .001$) effect of SES on internalizing problems was explained through maternal depression and parenting practices. Affect sizes are small but statistically significant. A positive relationship between mother and child as well as parental disciplinary practices are related to fewer emotional difficulties in children ($d = 0.02$, $p < .001$ and $d = 0.01$, $p < .001$, respectively)
Nicholson et al. (2012) Children of 0 to 3 years of age broadly represent the Australian population	To determine at what age physical and developmental health outcomes are impacted when children experience early and persistent low SES	Longitudinal cohort study	• SES using a composite variable: Parental income, education, and occupational prestige • Developmental health indicators: Socioemotional competence, socioemotional difficulties (measured at 2–3 years of age)	• Identified socioeconomic groups 1 to 5 with 1 being the least disadvantaged and 5 being the most disadvantaged. Social-emotional difficulties measured at 2–3 years of age, OR 2.7 (CI 2.1–3.5) for group 5 compared to 1.3 (CI 1.0–1.8) for group 2 ($p < .001$) • No moderation of relationship between SES and social-emotional development examined
Zilanawala, A. and Pilkauskas, N.V. (2012) Children of 3 years of age in 20 large cities in the USA. Sample was racially diverse with mainly low-income mothers	Is material hardship associated with child socioemotional behavior? Are there differences by developmental timing? Are particular hardships more strongly associated with child behavior? Are there differences in the association between short- and long-term material hardship and child behavior?	Longitudinal cohort study	• Material hardship: Utilities, food and medical bills, housing instability • Covariates: Household income-to-needs ratio, mother's education, employment status, parental marital status • Internalizing behaviors	• Children experiencing material hardship at 3 years of age are associated with higher levels of internalizing behaviors such as anxiety, depression, and withdrawal with SD 6.04 ($p < .001$) • Mother's impulsivity and maternal depression are both strongly associated with higher internalizing scores for 3-year-old children ($b = 0.33$, $p < .001$ and $b = 0.15$, $p < .05$, respectively)

of moderation of the relationship between SES and social-emotional development. Flouri et al. (2010) utilized three measures of temperament for children at age of 9 months and again at age of 3 years. Broad and specific psychopathology was assessed with reporting by the child's main caregiver using the 25-item Strengths and Difficulties Questionnaire (Goodman, 1997). Three dimensions were measured in the Millennium Cohort Study using the Carey Infant Temperament Scale (Carey and McDevitt, 1978); these include mood, adaptability to different situations, and regularity of physiological functions. Findings revealed no relationship between the geographic-area IMD and prosocial behavior, emotional problems, or peer problems. However, the effect of family SES on social-emotional development (prosocial and peer problems) was significant. Their analysis revealed no moderation of the relationship between SES and social-emotional development; however, the relationship between family SES and psychopathology more generally was moderated by child characteristics (e.g., age, sex) and family adversity.

Kiernan and Huerta (2008) assessed behavioral adjustment at age of 3 years using the 25-item Strengths and Difficulties Questionnaire (Goodman, 1997). This questionnaire assesses behaviors associated with emotional symptoms or internalizing behaviors such as often unhappy or tearful, nervous or clingy in new situations, easily loses confidence, and easily scared. Findings revealed that children living in low-SES families have a higher risk of experiencing internalizing behavioral problems (0.18 *SD*; $p < .001$). Children whose mothers are depressed tend to experience more internalizing behaviors ($d = 0.13$, $p < .001$). Total direct ($d = 0.10$, $p < .001$) and indirect ($d = 0.03$, $p < .001$) effect of SES on internalizing problems was explained through maternal depression and parenting practices. Affect sizes are small but statistically significant. A positive relationship between mother and child as well as parental disciplinary practices are related to fewer emotional difficulties in children ($d = 0.02$, $p < .001$ and $d = 0.01$, $p < .001$, respectively).

Nicholson et al. (2012) used the Brief Infant-Toddler Social and Emotional Assessment Problems scale as a tool to identify children at risk for developing social-emotional problems and those who are currently experiencing social-emotional difficulties (Briggs-Gowan et al., 2004). This scale is based on parental report of a 31-item scale of internalizing behaviors (anxiety and depression) in children from 12 to 35 months and 30 days old. This scale includes items such as restlessness, looks for a parent when upset, and has less fun than other children. Nicholson et al. (2012) identified socioeconomic groups 1–5, with 1 being the least disadvantaged and 5 being the most disadvantaged. Social-emotional difficulties measured at ages 2 to 3 years indicated the odds ratio (OR) was 2.7 (CI 2.1–3.5) for group 5 compared to 1.3 (CI 1.0–1.8) for group 2 ($p < .001$). In other words, greater disadvantage was associated with higher odds of poor social-emotional development. Group 5 (most disadvantaged) showed an OR (odds ratio) of 2.7 (2.1–3.5) for 2–3 year olds compared to OR 1.3 (1.0–1.8) for the least disadvantaged group. There was no moderation of the relationship between SES and social-emotional development in young children.

Zilanawala and Pilkauskas (2012) conducted interviews at birth and when the children were 1 and 3 years old and an in-home study when the children were 3 years old. They utilized the Child Behavior Checklist (Achenbach, 1992) to assess anxious/depressed and withdrawn behaviors such as sadness, nervousness, worry, affection, and interest. Moreover, children's positive behaviors were assessed using the abbreviated Adaptive Social Behavior Inventory (Hogan et al., 1992) at 3 years of age, including social competence and prosocial skills with adults and peers. They reported that children whose mothers report any material hardship had significantly higher levels of internalizing behaviors. Children experiencing material hardship at 3 years of age are associated with higher levels of internalizing behaviors such as anxiety, depression, and withdrawal with *SD* 6.04 ($p < .001$). Mother's impulsivity and maternal depression are both strongly associated with higher internalizing scores for 3-year-old children ($b = 0.33$, $p < .001$ and $b = 0.15$, $p < .05$, respectively).

Discussion

Four longitudinal birth cohort studies focusing on the effects of SES on social-emotional development of young children fulfilled the search criteria of this article. While this provided a small set of papers for inclusion, the samples represented in the papers included over 31 000 children and only included studies with broader conceptions of SES than income. While all papers relied on parental report of children's social-emotional development with the addition of direct child assessment or teacher report by Nicholson et al. (2012), it is difficult to study children's development in isolation of parenting and the parent–child relationship (Shonkoff and Phillips, 2000). Low SES is directly related to stress, and stress invariably impacts parenting and the home environment (Linver et al., 2002; McLoyd, 1998). Evidence suggests that the emotional environment of the home often influenced by complexities such as marital dysfunction, negative parent–child relationships, coercion or abuse, or mental illness in the parent affects how children learn to interpret and express their emotions. As a result of these complexities, the parent may not be readily available to help children manage often confusing and overwhelming emotions they may experience (Bradley and Corwyn, 2002; National Scientific Council on the Developing Child, 2011). Consistent with these observations, this article revealed moderation of the relationship between SES and social-emotional development by maternal depression, maternal impulsivity, and qualities of the parenting environment such as parent–child relationships. Findings point to implications in two areas, including the need for policy development reflecting early intervention and income subsidy, both as means to limit the effects of low SES on the social-emotional development of young children. As well, the home environment must be considered as a source of influence on social-emotional development in young children.

Policy Development: Early Intervention and Income Subsidy

All four studies support the need for policy development in two critical areas: early intervention and income subsidy. Nicholson et al. (2012) advocated for effective early intervention

programs aimed at reducing inequalities in early childhood. Unintentional benefits may occur as a result of targeting even one area of childhood development. For example, a child may experience improvements in social development when the intervention is focused on literacy. Kiernan and Huerta (2008) emphasized that without early intervention, early childhood adversity is likely to have long-lasting effects on children's social-emotional development. Flouri et al. (2010) suggested their findings – young children who experience family adversity are at a higher risk of emotional difficulties – can be used to inform early interventions.

Nicholson et al. (2012) and Zilanawala and Pilkauskas (2012) support the notion that raising income or providing in-kind assistance alone will lead to beneficial social-emotional development outcomes in children. Zilanawala and Pilkauskas suggest there is potential for a return on public investments if material hardship for low-income families (such as food insecurity and housing insecurity) is improved through cash transfer programs when children are in the early stages of development.

Home Environment

The findings of Zilanawala and Pilkauskas (2012) suggest that while income alone does not significantly predict social-emotional development (anxiety and depressive characteristics), broader characteristics of the home setting such as food insecurity and housing insecurity are associated with poor social-emotional development in children. Flouri et al. (2010) also determined that family SES significantly predicted not only social-emotional development in young children but also child psychopathology. Moreover, family SES predicted development directly and independently of maternal education and family adversity; however, when child-level characteristics (such as gender and age) were added to models, the effect of family SES on emotional symptoms became nonsignificant. Adversity within the family was also found to be a stronger predictor of child psychopathology than family SES, even when child-level characteristics were added (Flouri et al., 2010). These findings suggest that early interventions could target characteristics of the home environment. Kiernan and Huerta (2008) reinforced the critical impact of the home environment, as their results indicated children living in low-SES families have a higher risk of experiencing internalizing behaviors; however, a positive relationship between mother and child and parental disciplinary practices may mediate emotional difficulties.

In conclusion, while it is well known that chronic exposure to adversity has a significant impact on all forms of development (Edwards et al., 2003; Ladd et al., 2000), this article focused on the earliest stage of social-emotional development, which underpins other forms of development. Clearly, findings revealed that SES (composite definition) begins to have a negative impact on social-emotional development early in life. From birth to age of 3 years is a time to develop relationships, regulate and express emotions, form close and secure interpersonal relationships, and explore the environment and learn – all in the context of family, community, and cultural expectations for young children (Fitzgerald et al., 2011). Embedded in the interpretation of SES and socioemotional health is a cultural context that varies across and within cultures that cannot be ignored. However, there are fundamental standards central to child development regardless of culture (Maggi et al., 2010). Infant mental health, which sets the stage for future mental health, is shaped by environmental exposures during this critical and sensitive period of development (DiPietro, 2000; Siddiqi et al., 2007).

The small set of papers uncovered in the review suggests a need for more study to examine the relationship between broader conceptions of SES and young children's social-emotional development within the context of cultural competence. Perhaps even more important is the utilization of randomized control trials and the examination of moderating variables that can provide guidance for interventions and policy to address the impact of low SES on children's social-emotional development globally.

Abstract

Sociolinguistics is the study of the relationship between language and society. Sociolinguists may investigate linguistic variation correlated with social categories, style, or attitudes; the use of language in interaction to affirm the relative status of participants, norms of interaction and audience, or the social construction of self; the development of languages in contact; or the efforts of society to regulate linguistic choice through education or language policy and planning.

Sociolinguistics is the study of the relationship between language and society. As in any hyphenated or hybrid subdiscipline, work described as 'sociolinguistics' ranges along a continuum between two poles, which at their most extreme serve more as idealized points of reference than as widespread types of practice. Toward the linguistic end, analysts investigate the linguistic variation that results from determinants of language change that may or may not be socially driven (and such variationist researchers may suggest that their work should be called linguistics, not sociolinguistics). Research in this area is sometimes termed social (or urban) dialectology, and is most often identified with the theoretical and methodological school developed by William Labov. Toward the socio end, analysts may investigate the social meaning and relative status of different language varieties, without necessarily dealing with the linguistic structure of those varieties. A well-known early researcher in this area is Joshua Fishman, who has labeled such work 'the sociology of language.' Somewhere in the middle of the socio/linguistic continuum we find research on how language is used in interactions, an area that includes work on style shifting, discourse, and pragmatics. Journals and conferences devoted to the field can be positioned along the continuum, but often include research from a wide range of research approaches.

This article will attempt a similar inclusive approach. The first section provides a brief description of language-focused variationist work; the second describes some research on language use in interactions; the third considers the role of language in the social and sociological realm.

Social Determinants of Language Choice: Change, Variation, Community

Although language researchers have approached the topics of speech communities and the effect of social categories on language behavior for a century, an identifiable subfield called sociolinguistics truly emerged in the middle of the twentieth century. Fischer (1958) observed class, gender, and stylistic correlates to schoolchildren's use of alveolar (ING) (e.g., *swimmin'* instead of *swiiming*). But it is the pioneering work of William Labov, from *c.*1963 onward, that establishes the research questions, methodology, and analytical techniques of (variationist) sociolinguistics. In a series of influential, large-scale quantitative studies in Martha's Vineyard and New York City, Labov (1963, 1972) demonstrated that linguistic variation was not random ('free') or peripheral noise, as linguists had often assumed, but rather systematically patterned. The choice between two or more linguistic *variants* (ways of saying the same thing, referentially speaking) was affected by speakers' relevant social categories (e.g., age, social class, gender, or ethnicity), the formality of their speech style, and their attitudes toward the social groups associated with each variant. Furthermore, speakers shared linguistic norms, in terms of both overt attitudes (toward variants and their users) and a less overt and possibly subconscious sense of which variant was appropriate for particular speakers in a particular situation. Labov proposed the term *speech community* to describe large groups whose members shared such norms.

Much early work was designed to illuminate the regularities of non-mainstream speech, and to develop models to explain historical developments by observing language change as it occurred ('using the present to explain the past'). As technological advances eased natural recording and large-scale multivariate analysis, Labov and others developed methodological and analytical techniques and principles that are still in use today. These include interview techniques designed to elicit the most natural speech possible and to vary participants' degree of attention to their own speech (by recording speakers reading word lists or reading passages, in addition to participation in interviews). One powerful concept has been the *apparent time hypothesis*, the idea that differences between generations at one point in time reflect a snapshot of ongoing community-wide change. Subsequent work by Lesley and James Milroy in working-class Belfast developed social network techniques ('friend of a friend') to find and record community members whose frequent interactions encouraged linguistic similarities. They defined networks in terms of their denseness and multiplexity, showing that people who were most integrated into their local community networks were also the most likely to use more vernacular forms, and to resist imported language changes (Milroy, 1980). Yet more recent work has borrowed concepts from education and anthropology to adopt a more local focus, that of the community of practice (Eckert and McConnell-Ginet, 1999), investigating how norms are created and reinforced through interactions.

Variationist studies across communities and languages have replicated many of the field's original findings. Generally,

women lead language change and are more likely to use standard forms in situations of stable variation. The language of higher-status social classes is generally seen as desirable, and speakers of all classes tend to move toward that end of their repertoire in situations of heightened attention to speech. However, the countervailing appeal of working-class forms (*covert prestige*) leads to the maintenance of such variants, as speakers benefit from their associations with authenticity (Trudgill, 1972). Real-time studies have shown that most speakers maintain consistencies in speech across their lifespan, supporting the premise underlying the apparent time hypothesis, although some movement in the direction of incoming variants is often found (Blondeau et al., 2002). The social categories that influence speech (gender, ethnicity, social class, age, etc.) often interact in complex ways that may vary depending on the community (e.g., the sociolinguistic meaning or performance of gender may vary by ethnicity, or that of ethnicity may vary by gender). In addition, specific social traits – everything from occupation to political affiliation – may be relevant in particular communities, or at particular times. This is particularly evident in community of practice work, most notably in Eckert's (2000) influential sociolinguistic description of a suburban Michigan high school, where use of incoming vowel changes was highly dependent on how speakers situated themselves with respect to two school-specific social groups, the jocks (who reflected or respected mainstream or middle-class social norms) and the burnouts (who did not).

Variationists study variables that differ in their degree of salience to community members (e.g., stereotypes versus subtler sociolinguistic markers, which speakers can control when they shift linguistic styles, and yet subtler sociolinguistic indicators, which are beyond or below speaker control, but whose rate of use varies from one speaker to another). Variables can also be drawn from a range of linguistic domains, from tiny changes in vowel position (Labov et al., 2006) to the choice between discrete verbal markers or even lexical or discourse variables such as incoming quotative *be like* (as in *I was like, Oh my God!*) (Buchstaller and van Alphen, 2012).

In addition to the community norms revealed by language use, sociolinguists have investigated norms revealed through attitudes toward variants, languages, and speakers. The vernacular speech of New York City and the American South, for example, is widely stigmatized, especially by speakers of Midwestern American varieties (Preston and Howe, 1987). And covert linguistic attitudes have been revealed through matched guise techniques (in which naïve judges believe they are hearing different speakers, when in fact they are hearing the same speaker adopting the features of different language varieties). Across communities, researchers find that traits ascribed to speakers of standardlike varieties form a cluster associated with status (employability, intelligence, competence), while speakers of nonstandard or lower-status varieties are ascribed traits associated with solidarity or approachability (friendliness, warmth, authenticity) (Lambert et al., 1960). There are profound real-world applications of this work, as speakers of particular ethnic varieties are consistently rated as less suited to higher-status employment, or are denied access to housing (Purnell et al., 1999).

Language in Interaction: Status, Solidarity, Style

Another broad branch of sociolinguistics investigates how language is used in interactions, reflecting the relative status of participants, the norms of interaction and audience, and the social construction of self through linguistic choices and changes.

Status and Solidarity

The status/solidarity distinction described in language attitude work (see Section Social Determinants of Language Choice: Change, Variation, Community) also holds in studies of language in interaction. Many languages feature distinct variants that are expected when addressing an interlocutor of higher status or social distance. These can include *V forms* of the 'you' pronoun (e.g., *vous, Sie*), or the use of formal language, or the interlocutor's last name and/or title (*Dr Van Herk*). Other features are expected when speaking to somebody of lower status, or to whom the speaker is socially close. These include *T forms* (e.g., *tu, du*), informal language, and first-naming (*Gerard, dude!*) or nicknames (*G-man!*). The choice of forms expresses the participants' understanding of the power imbalance and/or intimacy of the relationship. Related work on politeness in speech (Brown and Levinson, 1987) identifies two competing goals of participants: to respect the right of the interlocutor to operate freely or be left alone (negative politeness), and to express rapport, solidarity, or friendship (positive politeness). The relative importance placed on each politeness type can vary by culture, leading to misunderstandings (as when the negative politeness strategies of Korean-American shopkeepers are interpreted as hostile by positive-politeness-valuing African-American customers) (Bailey, 1996). Societies may also differ, of course, in deciding which social boundaries are to be privileged in valuing status and solidarity.

Power imbalances are also crucial to work in Critical Discourse Analysis, whereby researchers investigate how ideology and power are enacted and refined during everyday interactions and through public texts such as those found in the mass media (Fairclough, 1995). Discourse analysis methodology (critical or otherwise) usually involves a fine reading of short stretches of text, examining discourse-level features such as overlapping speech, turn-taking, interruption, or hedging (e.g., *perhaps, kinda*, or tag questions like *it's hot, isn't it?*). Much well-known work on such features grows from influential writings by Robin Lakoff (1975), who associated many such features with gender-based power imbalances. Sociolinguistic analysis of media texts and depictions is exemplified by Rosina Lippi-Green's (1997) close reading of the varieties of English used by Disney characters.

Interaction and Audience

The ability of speakers to adjust their speech to specific situations has been a research interest of linguistic anthropologists, who work near the boundaries of sociolinguistics and have influenced the discipline. Although speech may be used to reveal or perform power imbalances, conversations are also generally collaborative enterprises. By interpreting interactions

as jointly organized activity (Sacks, 1984), conversational analysis looks at how participants work to organize and ease exchanges, by choosing when and how to deploy resources like discourse pairs (question–answer), or a shared awareness of the roles and expectations of types of participants (e.g., customer, interviewer, teacher). Dell Hymes (1974) describes ways in which aspects of an interaction (such as setting, participants, emotional tone, or genre) can influence the language choices that speakers make. Work in this area also attempts to identify the components of specific speech events, or genre-related language choices. Work on genre has also recently become central to the highly quantitative field of corpus linguistics.

Sociolinguists, on the other hand, have tended to focus on the participants in an interaction, more than on other Hymesian factors (which may reflect in part the fact that much sociolinguistic data is drawn from a single speech type, the interview). An influential article by Bell (1984) relates intra-speaker differences (i.e., style shifting) to the speaker's understanding of audience: immediate audience members (addressees) have a greater effect on style shifting than more distant conversational participants, such as overhearers. In the terminology of Accommodation Theory (Giles, 1973), speakers may attempt to sound more like their interlocutors (i.e., to *converge*) through similar speech rate, vowel forms, or discourse markers to express solidarity. Or they may *diverge*, in order to differentiate themselves (for example, the working-class boys in Cheshire (1982) use even more nonstandard forms to their teachers than they do to their friends).

More recent work on interaction (and on sociolinguistic variation more generally) tends to focus on the agency of speakers, as they use language to build up or perform an identity, to decide how to present themselves to others. The social meaning of the linguistic/stylistic performance emerges from the performance itself, so that speakers can use language features for the social meaning they might carry, but at the same time each performance of identity subtly shifts the shared understanding of the meaning of the features used. In such a constructivist approach, speakers may choose to portray themselves differently in different situations, or for different audiences. This perspective problematizes long-held notions of authenticity, social categories, or even group consensus or membership. For example, speakers might use features associated with the language of a different ethnic group, in order to invoke the socio-symbolic associations of that group, a process generally referred to as 'crossing' (Rampton, 1995).

Code Switching

In interactions where all (or many) of the participants can use more than one language, we see processes similar to style shifting occurring across language boundaries, i.e., *code switching*. The term can be used for switches between varieties of a single language (for example, when a man talking about theater tickets with his wife on his cell phone suddenly switches into African-American English to maintain a masculine persona in front of other men), but it is generally associated with switches between (mutually incomprehensible) languages.

Sometimes, long stretches of conversation between bilinguals occur in a single language, if one or both participants evaluate the (Hymesian) requirements of the interaction as requiring that language. For example, a teacher might talk to a student in the language that their school uses for instruction, to maintain distance and to avoid claims based on shared social or linguistic group membership. This is usually referred to as *situational code-switching*. Other times, fully bilingual participants may shift rapidly and fluently between languages, even within a single sentence, based on the topic, or the impression they wish to convey, or even to exhibit linguistic skill or because such rapid switching has become the norm in their bilingual speech community. Such *metaphorical code-switching* requires a high degree of knowledge of the two (or more) languages involved, and seems to follow fairly strict linguistic rules on when switching can occur. Language mixing in bilingual communities often functions as a form of identity performance, establishing new hybrid cultures and cultural stances (e.g., in global hip-hop).

Language(s) in Society

Most of the world's humans are multilingual, as are almost all of the world's countries. In this section, I look at how sociolinguists study the consequences of languages in contact.

Societal Multilingualism

Through population movements and political decisions (e.g., the drawing of national boundaries across linguistic boundaries), most contemporary countries are populated by speakers of different languages. Such societal multilingualism can take many forms: in some countries, speakers of different languages occupy distinct regions (e.g., French and Flemish in Belgium). Other countries have large immigrant populations, who across generations are likely to move toward the host nation's language (e.g., Spanish and English in the United States). Still others have, for various reasons, maintained societal bilingualism across multiple generations, to the point where most of the inhabitants are fluent in two or more languages and use each one in different areas (domains) of their lives. Ferguson (1959) calls this *diglossia*, and describes how one language (the H or High language) tends to be used in the courts, government, schools, literature, and education, while the other (the L or Low language) is generally associated with the domains of home, the street, or perhaps humor. In Paraguay, for example, the local language Guaraní might be used in rural areas, or with intimates, while Spanish is more common in urban areas, in formal contexts (Rubin, 1968). Work since Ferguson has broadened the concept of diglossia to include more multilingual contexts where domain is significant, and nuanced the original framework to account for some fluidity. Even in diglossic situations, for example, speakers can use the 'wrong' language to lighten up a conversation, or to invoke borrowed connotations of authority or authenticity.

Diglossic situations may involve the maintenance of individual multilingualism over multiple generations, but it is more often the case (e.g., in the case of immigration) that generations will move from monolingualism in the immigrant language, to bilingualism, to eventual monolingualism in the target country language. This process of language shift

usually occurs across three generations, depending on the 'ethnolinguistic vitality' (Giles et al., 1977) of the community. Fishman (1991) describes a series of stages through which a language moves, usually domain by domain, from full vitality to eventual language death. In nonimmigrant language shift situations, smaller or endangered languages retreat to a single domain, the home, and even then eventually often for use only with or among older generations. Much sociolinguistic research on language revival has looked at how to slow the decline or disappearance of the world's less-spoken languages or to describe the 'linguistic imperialism' (Phillipson, 1992) by which widely spoken languages of power and wealth displace such languages.

Language Contact

A common consequence of societal and individual multilingualism is that the languages used begin to influence each other. Some words from one language are used by code-switching bilinguals often enough that they become part of the other language, eventually adapted to suit the pronunciation and linguistic rules of the new language. Among the words that are at different stages of entering English (and may or may not be considered 'real' English words by different speakers), we might consider *boondocks* (from Tagalog), *mensch* (from Yiddish), or *desi* (from Punjabi and other Indic languages). Such borrowings make up a good part of the word stock of colonializing languages like English. Speakers can situate themselves with respect to language communities through the use of such words (or longer constructions such as the loan translation *I'm after telling him that* in Irish-influenced English).

In contexts where speakers are forced to communicate across language barriers but have limited access to a shared language, it is possible that a pidgin language will emerge. In situations of trade, or on plantations, a lingua franca will be needed to allow basic communication. Pidgin languages tend to be structurally simple, with small vocabularies taken from an economically or politically dominant language, and are intended for specific restricted purposes. When pidgin languages start to be used as first languages and for broader purposes, they are elaborated so that they can perform all the linguistic and interactional functions of a full language. They then become creoles. Well-known creoles include Nigerian Pidgin English, Haitian Creole, and Tok Pisin, the official language of Papua New Guinea. Linguists continue to debate (often hotly) the details of the origins and development of creoles, but generally agree on the full functionality of such languages and on the degree to which they are often stigmatized by nonspeakers unaware of their history or richness.

Social and Political Organization of Language

Societies and the institutions that they develop are often actively involved in determining the fate of the languages of their citizens, and these processes provide sociolinguists with both research material and the opportunity to see sociolinguistic findings used to inform policy.

Education is a particularly intense area of sociolinguistic debate. The value of bilingual education as a means to either maintain linguistic and cultural diversity or speed the integration of minority language speakers tends to be a politically loaded question, implicating as it does immigration policy, minority rights, and questions of national identity. Often, sociolinguistic research findings on bilingual education in one societal context are inappropriately heralded to support only vaguely similar policies in other, very different contexts, as societal multilingualism varies widely in its details from place to place. When it comes to the value to education of different varieties of the same language, the debate is no less intense. Influential early work by sociologist Basil Bernstein (1961) suggested that working-class children's dense social networks led them to develop a highly context-specific language variety, which he called a 'restricted code'; middle-class children's speech, on the other hand, was said to rely more on linguistic rather than contextual cues, leading to an 'elaborated code' better suited to the school system. Later sociolinguistic work revealed the richness of working-class speech, and suggested that the in-school uncommunicativeness of working-class students had more to do with differing sociolinguistic norms and limited (meta)linguistic awareness on the part of educators. It remains difficult to empirically gauge the pedagogical value of integrating home speech into classroom situations, due to social and political resistance to such domain crossing.

Another area of societal organization of language of interest to sociolinguists is that of language policy and planning. Governments and other social actors (schools, churches, writers, pundits, editors) make conscious decisions about which language(s) will serve which roles in a society. Status planning can decide the official language of the country, or of domains like education, law, or government. Different policies will encourage assimilation of minority language groups, or linguistic pluralism, or vernacularization (the promotion of a local language to official or national status), or internationalization (the choice of a nonlocal language as a 'neutral' lingua franca). Corpus planning can decide how a language should be changed (or not) to meet all the needs of the society, for example by creating new words and technical terms or by discouraging the use of borrowings from other languages (e.g., the *Office Québécois de la Langue Français*, which encourages the use of *le mot-dièse* 'word + musical-sharp-sign' rather than *le hashtag*).

Conclusion

Readers are encouraged to investigate more detailed articles on many of the topics discussed here (see below), or to get a broader overview of current sociolinguistics by consulting recent introductory textbooks (e.g., Coulmas, 2013; Mesthrie et al., 2009; Van Herk, 2012).

Hyphenated disciplines like sociolinguistics are capable of developing into many new areas over the next generation or two. We are already seeing promising work in a direction suggested or predicted by Suzanne Romaine (2001: 14568) in the first edition of this work ("the steady integration of macrosociolinguistic ('sociology of language') approaches with variationist and microsociolinguistic (interactional/DA) approaches seems a likely direction of development."). We are also beginning to see productive disintegration of these areas, with quantitative sociolinguists adopting the large-scale approaches and intense

statistical rigor of corpus linguistics, while researchers at the qualitative end productively collaborate with anthropologists and gender studies researchers. Speakers' agentive behavior is becoming more and more central to discussions of variation and style. And we can hope that, again in Romaine's words, "sound descriptive sociolinguistic research will continue to provide the critical underpinning for language policy developments in areas such as minority groups, immigration, education, and second language teaching."

Abstract

Sociological theorizing has dramatically expanded its explanatory range over the last years. Yet, certain enduring problems still divide theoretical work, namely, the questions of whether or not sociology can be a science, whether or not it should be normative and critical or value-neutral, and whether the appropriate level of analysis is micro or macro. Nine basic theoretical perspectives have evolved over the last decades, each with many variants. These perspectives include functional, evolutionary, ecological, conflict, exchange, interactionist, structural, cultural, and critical theoretical approaches.

Points of Fundamental Disagreement

From its beginnings in Europe and the United States, sociology has been ambivalent about whether or not scientific theorizing like that in the natural sciences is possible, or even desirable. There are several points of intense disagreement.

Can Sociology Be a Science?

This is perhaps the most hotly debated issue because it immediately affects the kind of theorizing that is done in sociology. If there is a belief that sociology can be a natural science, theorizing will seek to isolate the generic phenomena that drive all behaviors, interactions, and patterns of social organization in all times and in all places. Theorists will attempt to develop abstract theoretical principles or 'laws' as well as formal models of generic social processes. Conversely, if sociologists do not believe that sociology can be a science, theorizing will be a variety of intellectual enterprises: history of ideas, descriptions of current or past events, concepts describing phenomena, ideological advocacy, philosophy, and meta-analysis of social thought. There are many justifications for this kind of activity but the most fundamental is that human behavior, interaction, and organization are seen as fundamentally different from the domains of the universe studied by the natural sciences. The most central of these is that humans possess agency and can change the fundamental nature of social organization, thereby obviating any theoretical principles or models that are presumed to be about universal phenomena.

Should Sociological Theorizing Be Normative?

Many sociological theorists reject the notion of value-free science. Sociology and its theories should address problems of social organization – most importantly inequality and oppression. But, the correlation between advocacy and science is not perfect. Many contemporary scientific theorists view the development of scientific theory as a necessary step in creating more just societies. Others see themselves as scientists but of a special kind: scientists devoted to understanding the dynamics of inequality and oppression with an eye to using this knowledge to destroy oppressive arrangements. In contrast to this position are those who seek to explain the operative dynamics driving the social universe, per se, rather than as part of a social activist and value-laden agenda.

What Is the Appropriate Level of Analysis

Whatever the position of theorists on the scientific prospects for sociology, there has always been a debate over the level of analysis that will give sociological theories the most explanatory power. Early sociology was decidedly macro in its emphasis, although microthinking penetrated almost all of the founding generation of sociological theorists at some point. But during the twentieth century, theorizing split into three main camps (Turner and Turner, 1990): macro, micro, and mesotheorizing. These levels of theorizing correspond to the way the social universe actually unfolds. There is a microlevel of face-to-face interaction, a macrolevel of societal, intersocietal, institutional, and stratification analysis, and a mesolevel that tries to explain those structures that constrain microinteractions, while at the same time being the building blocks of the macrouniverse.

One of the main issues in sociological theorizing has been linking theoretical explanations across all of these levels. For scientifically oriented sociologists, just like scientists in physics, biology, and economics, the theoretical link is the holy grail of explanation. Those critical of science often note that the failure of sociologists to make this theoretical linkage is 'proof' that sociology cannot be a science, conveniently ignoring the fact that no science has thus far achieved this lofty goal. In light of some recent theories in sociology (e.g., Lawler et al., 2009; Turner, 2010–2013), sociology has achieved considerable integration across levels; and in fact, it could be argued that sociology is further along in finding the holy grail than any other science. But, this issue will remain controversial.

Despite these controversies, sociological theorizing has made dramatic progress over the last 40 years. There are more theories with more explanatory power than ever before. The progress presents a problem in how to cover the range of theories in this delimited space. The best way, indeed the only way, is to divide up theoretical activity into a variety of perspectives or approaches, with each approach addressing the controversial issues outlined earlier as it examines a particular range of phenomena in the social universe.

General Theoretical Perspectives in Present-Day Sociology

Naturally, it is difficult to divide up theoretical activities into truly discrete approaches, but there are still at least nine broad rubrics that organize theoretical sociology today, each with many variants. Moreover, theories within a rubric can come into conflict with other, while many theories listed under different rubrics can overlap. Such is the somewhat chaotic nature of theorizing in sociology (Turner and Maryanski, 2008).

Functional Theorizing

Functional theorizing was sociology's first major approach, introduced by Auguste Comte and carried forth into the early twentieth century by Herbert Spencer ([1874–1894]1898), Emile Durkheim (1893[1933]), and to the midpoint of the twentieth century by anthropologists at which point functionalism became sociology's dominant theoretical approach in the 1950s and 1960s, only to seemingly disappear in the contemporary era. All functional theories begin with a basic presumption (Turner and Maryanski, 1979): social systems have functional needs or requisites that they must meet if they are to adapt to their respective environments. Theoretical explanation is achieved when 'the functions' of particular subparts of a system are discovered and analyzed for why they evolved and how they operate to meet, or fail to meet, universal functional requisites. Early functional theories focused on societies as the unit of analysis, and thus they posited needs or requisites that societies must meet, with the analysis of institutional systems (e.g., economy, polity, kinship, religion) in terms of the societal-level needs that they meet. Herbert Spencer and Emile Durkheim can be seen as the two templates for functional analysis. Spencer posited three basic needs, needs for operation (production and reproduction), for regulation (through power and unifying cultural symbols), and for distribution (of people, information, and resources across territories); Durkheim posited one overarching need for integration. Thus, by determining how institutional systems meet multiple or singular needs, theoretical explanation is achieved. When functionalism appeared to die for the first time in the early 1900s because of its association with evolutionary models (see next section), it was carried forth by anthropologists, particularly Bronislaw Malinowski (1944) and A.R. Radcliffe-Brown (1952).

When functionalism was reborn in sociology during the 1950s and 1960s, Talcott Parsons became the dominant figure, arguing like Spencer that all systems of the social universe reveal four basic needs (Parsons et al., 1953): adaptation (taking in needed resources from the environment, converting them for use, and then distributing them); goal attainment (establishing system goals and mobilizing resources to meet these goals); integration (coordinating differentiated parts of the system); and latency (or managing tensions within and among parts of the system as well as reproducing system parts). Other contemporary functionalists like Niklas Luhmann (1982) adopted a more Durkheimian strategy in positing one master need: the need to reduce complexity of systems in their temporal, spatial and material, and symbolic environments.

Functionalism declined and then virtually disappeared because of a number of problems: it seemed to many to be a cover for a conservative ideology emphasizing the functions of the status quo; explanations seemed to be tautological (system parts meet functions for survival and this is known because the system is surviving); and illegitimate teleologies in which the historical origins of system parts are caused by their functional outcomes. Yet, functionalism has never been extinguished, and there are scholars openly working with functionalist schemes, often downplaying the emphasis on system requisites in ways that mute the criticisms of this approach.

Evolutionary Theorizing

Revival of Stage Models

When evolutionary theorizing died in the first decade of the twentieth century, it did so because of the racism and ethnocentricism associated with viewing European societies as the most advanced compared to 'primitive,' preliterate peoples. Functional models of evolution, as well as conflict models like the one developed by Karl Marx, all saw societies as moving through a series of evolutionary stages from simple hunting and gathering through horticultural (plus pastoral and fishing variants) and agrarian stages, to the pinnacle of societal evolution: western industrial societies. When evolutionary theory reemerged in the 1960s (Lenski, 1966; Parsons, 1966, 1971), it came back in a much more sophisticated guise, with sensitivity not evident among nineteenth- and early twentieth-century theorists. More emphasis was placed on the mechanisms driving evolution, such as population growth, technological development, warfare, and ecological pressures. With the revival of stage model evolutionary theorizing, functional analysis crept in the back door with theorists emphasizing that societies become more complex as they confront selection pressures along a number of axes, such as population growth, environmental degradation, insufficient production, problems in reproduction, pressures to regulate conflict and complexity, and problems in distributing resources, information, and people across larger territories controlled by more complex sociocultural systems (Turner, 2010–2013).

The Darwinian Revival

At the same time these new stage-model evolutionary theories were coming back into vogue, new more explicitly Darwinian-inspired theories from outside sociology proper were being posited as an alternative way to explain sociocultural phenomena. Ironically, evolutionary theorizing had been rejected in the 1920s and 1930s because of the spread of Social Darwinism, but the revival of Darwinism was now purely biological, but nonetheless threatening to sociologists. These Darwinian approaches have been rejected by many sociological theorists, but a new field of theoretical sociology – loosely called 'evolutionary sociology' – has emerged to embrace and import models from biology, including sociobiology and evolutionary psychology, or to provide an alternative that is equally steeped in biology without the unfounded assumptions of sociobiology or evolutionary psychology (see Turner et al., 2014 for examples). This alternative is willing to consider the genetic

basis of human behavior as a result of selection pressures, but it adds many of the general ideas of contemporary stage-modeling evolutionary theories, such that pressures from genes are only one of many selection pressures. Equally important, many of these other selection pressures come from problems of organizing among humans' hominid ancestors in new ecological environments. There has often been considerable debate and even hostility among the various camps of more Darwinian evolutionary theories in sociology, but it is clear that biology is back in sociology and will continue to be an important line of theory and research.

Ecological Theorizing

In both Spencer's and Durkheim's functional and evolutionary theorizing we find another kind of biologically inspired approach: ecological theorizing that became firmly a part of sociological theory in the United States during the 1930s. Drawing from Darwin's key idea of natural selection, the basic arguments in all ecological theories are much the same: social units compete for resources within niches of resources that are necessary for their survival; and those that possess traits that enhance their capacity to secure resources and reproduce themselves will survive, while those that cannot, will die out or be forced to move to a new resource niche. Like Darwin and later Durkheim, ecological theories emphasize that as the number of units in a resource niche increases, density increases the level of competition; at some point, the niche cannot carry all of the units competing for resources. Thus whether considering the distribution of people and types of social units in urban areas (Niemela, 2011; Berry and Kasarda, 1977), where competition is institutionalized in the real-estate market, or the life and death of organizations competing for resource shares in dense niche (Hannan and Freeman, 1989), Darwinian processes are the driving force and can explain many of the dynamics of urban areas and populations of organizations. Some have even taken ecological theorizing back to the macrolevel by emphasizing that the relations among societies in their common environments can be understood in ecological terms (see, e.g., Hawley, 1986).

Conflict Theorizing

Conflict theorizing has always been part of sociological theory. For a time in the 1960s and 1970s, conflict theorizing became a self-labeled school of thought to use as a foil for attacking the weaknesses of Parsonsian functionalism. Indeed, during the period from 1960 to 1990, power and conflict were dominant topics in sociology, just as they had been for the founding masters in the classical tradition. Over the last few decades, however, the label conflict theory has receded as the basic substance of the approach has become a part of so many other theoretical traditions.

The central argument of all conflict theories is that inequalities in social systems generate tensions that, under specifiable conditions, lead subordinates in a system of inequality to mobilize for conflict against superordinates and, thereby, to change the structure and culture of a social system. Most conflict theories have been couched at the macro, societal level but in recent years, the approach has been extended to even more macrolevels in world systems theorizing (Wallerstein, 1974–1989; Chase-Dunn, 2001) and down to the microlevel of face-to-face interaction (Collins, 2008). In conflict theorizing, one also sees the diverse epistemological positions of sociology in play. Some are decidedly scientific and analytical; others are more historical and descriptive while being more abstract and analytical than most histories; still others are more normative and advocate particular forms of conflict to achieving value-laden end states; and a few are both. In all, the legacy of Max Weber and Karl Marx is prominent.

Analytical Conflict Theories

The first conflict theories to attack functionalism were analytical, often making Marx's model more abstract and adding qualifications of Max Weber and Georg Simmel (Dahrendorf, 1959; Turner, 1975, 2010–2013). These theories emphasized that conflict occurs in all social systems under specifiable conditions, including the level of inequality, abusive practices of superordinates, emergence of leaders, codification of grievances into ideologies and emotional arousal of subordinates, and mobilization of material and organizational resources to pursue conflict. These analytical theories converged with resource mobilization theories developed by those studying collective behavior (e.g., McCarthy and Zald, 2001; Zald and McCarthy, 1987; Tilly, 1993). Some analytical theories were more Weberian in origin and have sought to explain conflict at all levels of social organization in terms of variables central to Weber's theory, such as the multiple bases of inequality among different types of social units at varying levels of social organization (Collins, 1975, 2008; Turner, 2012).

Marxian Conflict Theories

Alongside these more scientifically oriented analytical theories can be found a variety of Marxist theories. These theories often became conflated with various types of 'critical theories' (see later sections) using Marxian ideas to criticize various socio-cultural conditions in modern societies and to advocate for particular types of change. Many downsized Marxian ideas to particular topics such as ethnic and gender inequalities (e.g., Bonacich, 1972; Chafetz, 1990) and developed critical analyses of these more specific forms of inequality. Still other approaches shifted the unit of analysis from societal social systems, where Marx's predictions failed, to the dynamics of intersocietal systems, where these predictions would seem more likely to occur as capitalism became global and the contradictions of capitalism would play themselves out and cause crises that might usher in socialism (Wallerstein, 1974–1989; Chase-Dunn, 2001). During this entire period from the 1960s to the present, Marxists have continued to wrestle with the question of why Marx's predictions about capitalism – polarization into two classes, mobilization for conflict by the proletariat, and the overthrow of capitalism – did not occur in any capitalist society. To address these failures in Marx's predictions, these Marxian approaches examined the problems of proliferating classes, the problem of conceptualizing exploitation, the contradictory class locations of persons and families, and other occurrences that went against Marx's

predictions (Wright, 1997), often culminating in advocating for a less Marxian view of socialism as the most realistic utopia (Wright, 2010).

Comparative-Historical Conflict Theories

During the entire period since the 1960s, when conflict theory began to attack functionalism, historical and comparative analysis of conflict, particularly revolutions, became highly prominent. These theories add new variables to the conflict model, such as the conditions causing the weakening of the state that makes it vulnerable to revolution and the demographic, ecological, geographical, and economic conditions in (mostly feudal) societies that increase revolutionary potential (Tilly, 1993; Skocpol, 1979; Goldstone, 1990). Much of this comparative-historical work also involved blending theories from collective behavior, especially from resource mobilization theories (McCarthy and Zald, 2001) with Marxian and Weberian conflict theories to particular historical cases in order to explain the mobilization of subordinates for conflict.

Microlevel Conflict Theories

In recent years, theorists like Collins (2008) have begun to explore the dynamics of interaction in conflict. These theories try to explain why and through what interpersonal processes individuals become violent or willing to be violent in various types of conflict – from crowd behaviors through combat units engaged in war to terrorist acts, often emphasizing the biosocial forces arousing various types of emotions and the interactional dynamics that lead to mobilization for conflict. These theories stress that acts of conflict, even when well organized in mobilized armies, do not assure that all combatants will actually engage in violence, thereby qualifying more meso- and macrolevel theories of conflict. Conflict mobilization and actual violence are ultimately interpersonal processes revolving around the arousal and then channeling of emotions (Collins, 2008).

Exchange Theorizing

For many decades in the nineteenth and twentieth centuries, sociologists were equally distrustful of utilitarian or neo-classical economics and psychological behaviorism, even though both contain the seeds for what became known as exchange theory in the 1960s. These exchange theories relaxed if not rejected many of the key extreme assumptions of neo-classical economics (e.g., actors seek to maximize utilities) and behaviorism (e.g., thinking and decision-making cannot be directly observed and, hence, theorized), while sustaining the basic idea that individuals and collective actors seek resources that bring rewards and reinforcement. In all sociological exchange theories, actors are seen to calculate the costs and investments in securing resources; and when the resources received exceed the costs required to procure them, individuals experience positive emotions and become willing to form more permanent exchange relations. Increasingly, exchange theories began to emphasize that, from these basic exchange dynamics, the meso- and macrolevel social structures of human societies are ultimately built up.

Exchange theories typically began with either behaviorist or utilitarian assumptions but, as they relaxed the extremes of these theoretical approaches, they converged into a set of theories emphasizing that both solidarity and conflict in social relations are related to exchanges of resources among individuals and collective actors. As these theories developed, additional dynamics were added to exchange, including inequalities in the relative power of actors (Blau, 1964; Emerson, 1962), calculation of not only costs and investments but also fairness and justice in exchanges, emotional arousal as an outcome of justice, commitments to exchanges (Cook and Emerson, 1978; Lawler and Yoon, 1996), and commitments to macrolevel structures (Lawler et al., 2009).

There is now a variety of general approaches to exchange theorizing that, in somewhat different ways, incorporate the above considerations into models and theories, all of which are committed to the epistemology of science. The most prominent are rational choice theorizing, which extends across the social sciences, and exchange-network theorizing, which remains more uniquely sociological.

Rational Choice Theories

This approach often retains the neo-classical notion that individuals seek to maximize their rewards, relative to costs and investments, but even with this rather extreme assumption, the approach attempts to explain sociological phenomena in terms of the underlying rationality of actors. One basic argument within sociology (Coleman, 1990) is that it is often rational for actors to give up certain rights in order to avoid what are sometimes termed negative externalities (or punishments and negative outcomes) by agreeing to abide by norms or to give authority to certain actors. It is rational to do so because, in avoiding negative externalities, the costs of giving up rights are less than the punishments that come with negative externalities. Thus, power and normative systems evolve in human social systems as rational actors seek to reduce negative externalities and, thereby, maximize the rewards that come with more stable patterns of social organization.

Social solidarity and group cohesion are also topics examined by rational choice theories (Hechter, 1987). Group solidarity, for example, can be explained by the degree to which individuals are dependent upon groups for receipt of intrinsic rewards or private goods created by interactions in the group; these are often very valuable and not easily secured elsewhere or only at high costs. Thus, it is rational for actors to monitor and sanction each other and to create normative systems that require individuals to contribute to group activities and, thereby, receive not only the rewards produced by this activity but also the additional rewards that come with a sense of group solidarity and other intrinsic reinforcers. Thus, seemingly normative processes can be explained by the rationality of actors. Conversely, when individuals participate in groups for extrinsic rewards alone, it is rational for them to free-ride or do as little work as possible, thereby forcing organizations to create more formal systems of monitoring and sanctioning, thus, reducing group solidarity but, nonetheless, reducing free-riding. Even though authority and normative systems impose costs on patterns of social organization, it is rational to create them in order to

sustain productivity of group members for whom it would otherwise be rational to free-ride.

Exchange-Network Theories

This theorizing blends network theory (see later text on structural theories) with exchange theory, while making power central to the exchange process. It also emphasizes that it is the nature of the relationship rather than the properties of actors that is to be subject of theorizing. Whether individuals or collective actors, the same basic exchange dynamics operate; and these revolve around the forms of relationships generated by power inequalities (Emerson, 1962). The more one actor controls resources that other actors value, the more dependent are the latter on the former, thus giving power to an actor who possesses valued resources. Thus, the power of actor A over actor B is a function of the dependence of B on A for a valued resource. Actor A will use this power and increasingly demand more resources from B; and this exploitation of B by A sets into motion balancing operations by B to shift the balance of power by several means: Offering new resources valued by actor A; joining in coalitions of Bs against A and/or cutting off alternative sources of the resources to A; doing without the resources offered by A; seeking alternative As or new sources for a valued resource; and other strategies that reduce dependence of Bs on As.

Also within this exchange network tradition, more interpersonal processes have been examined, in particular emotions, commitments to exchange relations, and commitments to macrostructures. The basic argument is that the more equal exchanges of resources are, the more positive are the emotions of actors; and over time positive emotions create commitments to a relationship and, ultimately, to macrostructures, especially when individuals are engaged in joint productive activities where each actor's contribution is difficult to determine, resulting in group solidarity that travels up networks of embeddedness among social structures that produce commitments to societies as a whole (Lawler, 2001; Lawler et al., 2009).

Convergence of Exchange and Conflict Theories

Some early exchange theories (e.g., Blau, 1964) made explicit the similarity between Marx-inspired conflict theories and exchange theories. In fact, conflict theory might be seen as a variant of exchange theories because conflict emerges with inequalities of power, in which the powerful exploit the less powerful and extract unfair and unjust rewards from subordinates. Such exploitive exchanges arouse negative emotions and set into motion conflict dynamics revolving around the ideological mobilization of subordinates to form conflict groups and redress their grievances through conflict.

Interactionist Theorizing

Early sociological theorizing was decidedly macro in its focus, but signs of a more microlevel orientation could be found in Spencer's ([1874–1894]1898) analysis of ceremonial institutions, Weber's (1968[1922]) later turn to verstehn analysis and types of action, Durkheim's (1963[1912]) increasing concern with emotion and rituals, Simmel's (1956 [1903]) analysis of self in groups, Alfred Schutz's (1967 [1932]) phenomenology, and most importantly Charles Horton Cooley' (1902) and George Herbert Mead's (1934) analysis of self and interaction processes. Present-day interactionist theorizing has now differentiated into several distinct lineages of theorizing.

Symbolic Interactionist Theories

Drawn from Cooley and Mead, symbolic interactionism now emphasizes the significance of self and identity processes. Self is increasingly conceptualized as a series of identities that individuals seek to verify in interactions with others; and depending upon whether or not verification occurs, persons will experience either positive or negative emotions (Burke and Stets, 2009). There are many variants of these identities theories, but most emphasize that there are several levels of identity, including core or person identities, social identities, group identities, and role identities. These are often conceptualized as a hierarchy with a persons' core feelings and cognitions about self being the most general, social identities attached to membership in categories (gender, ethnicity, age, etc.) as the next most general, group identities or attachments to corporate units being the next most general, and finally, role identities being the least general. To some extent, these various levels of identity are interconnected, with verification of an identity at one level having effects on confirming an identity at another level.

Some symbolic interactionist theories (e.g., Scheff, 1997; Turner, 2002, 2007) introduce psychoanalytic dynamics, emphasizing that individuals will often repress negative emotions like shame and guilt when their identities are not verified. With repression, the dynamics of emotion often disrupt interpersonal processes, while having potentially large effects on people's commitments to macrostructures in a society.

Dramaturgical Theories

This form of interactionist theorizing draws more from Durkheim's analysis of emotional-arousal rituals than from Cooley and Mead. The principle difference between symbolic interactionism and dramaturgy is that self and identity are viewed as more situational and transitory in dramaturgy than in symbolic interactionism. Self is something that individuals 'put on' for a particular presentation to others in a social situation rather than being a regulating gyroscope for behavior. Indeed, in dramaturgical theorizing, individuals often put on rather disingenuous selves for particular strategic purposes. Erving Goffman (1959) was the originator of this form of theorizing, where episodes of interaction are much like a theatrical presentation with the script inhering in norms and determining the broad contours of roles that actors interpret with some dramatic latitude in their presentations of self to an audience of others. Interactions are also normatively regulated by rituals (Goffman, 1967) that open, close, form, and repair episodes of interaction on the social stage and they are constrained by frames that actors impose to specify what is to be included and excluded from interaction (Goffman, 1974). During the course of interaction, individuals categorize situations in terms of the relative amount of work – practical, social, or ceremonial content

they are to contain. They also determine through rituals and frames the normatively appropriate forms of talk, as well as types and levels of emotions to be presented to others.

While interactions are very much constrained by the normative script, they also involve a great deal of strategic behavior in the presentation of self, reference to norms, imposition of frames, and use of rituals, often for nefarious purposes. Thus, interaction is not solely driven by people's efforts to verify identities, as more recent identities theories might emphasize; it is a dramatic presentation drawing from a cultural script containing norms that, in turn, specify the appropriate roles, frames rituals, talk, and feelings. These elements that guide interaction are often manipulated in self-presentations.

Dramaturgy has gone in many directions since Goffman's analysis. One is into the sociology of emotions, where actors experience negative emotions when encounters of interaction are breached. Actors also use emotions for manipulative purposes to gain favor, respect, or even sympathy form others (Clark, 1997). Another is the analysis of interaction rituals for how they arouse emotions and, thereby, build up solidarity and culture in groups (Collins, 2004). Yet another line of dramaturgical inquiry is the analysis of an emotion culture, which imposes feeling and display rules (in the cultural script) that individuals do not feel and must, thereby, work at or engage in alienating emotional labor to present to others (Hochschild, 1979, 1983). Yet another line of analysis focuses on deviance and the emotional strategies used to cope with pressures from multiple roles, subcultural marginality, ambiguities in norms, and at times rigid rules governing rituals (Thoits, 1990).

Role Theories

In recent decades, role theorizing has declined, although several sociologists continue the tradition (e.g., R. Turner, 2001; J.H. Turner, 2002). Mead introduced the notion of role taking to emphasize the process by which individuals read the gestures of others to determine their dispositions and likely courses of action. They can role-take not only with others but also with generalized others, thereby plugging themselves into the culture of a situation. For many decades, roles were theorized, emphasizing that roles are behaviors emitted by persons by virtue of normative requirements and status locations of individuals in a situation. Ralph H. Turner (1962, 2001) developed a more robust conception of roles by emphasizing the compliment of role-taking, the process of role-making whereby individuals emit both conscious and unconscious gestures as they seek to make and establish a role for themselves vis-à-vis other roles in a situation.

Status Theories

Status theorizing began at about the peak of role theorizing in the 1950s and 1960s (Berger, unpublished). In status theories, emphasis is on the expectations associated with status in situations, with status being defined along three dimensions: authority at locations in the division of labor of a corporate unit, membership in a social category (diffuse status characteristic), and prestige or honor that people can claim by virtue of their status locations or diffuse status characteristics. For any status, there are moral evaluations of the 'worth' of incumbents that are codified into broader status beliefs in the culture of a society. These status beliefs constrain the expectation states for individuals in a given status; that is, for any status there are expectation states for how people should behave. For those with higher authority in status locations, for those with more prestige, and for those with more valued diffuse status characteristics, expectation states give them advantages in interaction; they are allowed to initiate more interactions, to have their views followed, and to receive deference and obedience for their prestige and authority. If, however, individuals do not meet the expectation states on them, they will experience negative emotions, while others will often negatively sanction them. The same is also true of lower status individuals; if they violate the lowered expectations states on them by, for example, challenging higher status persons, they will often be sanctioned by their fellow lower status peers (Ridgeway, 1994; Milner and Walker, 2014). Thus, status beliefs and expectation states create a status order in all interactions, thereby giving interactions stability over time and place. This research theory tradition has continuously expanded its reach over the last decades (for a summary review, see Wagner and Turner, 2013).

Another line of status theories emphasizes the power of expectations. Individuals are conceptualized as seeking power and status in interactions, but their emotional reactions in situations are related to their expectations for gains or losses in status and whether or not they met or failed to meet these expectations (Kemper and Collins, 1990; Webster and Walker, 2014). The higher the expectations for maintaining or gaining in status, and the less these expectations are realized, then the more individuals will experience shame, whereas the more they expected to gain in power but in fact lost power, the more they will experience anxiety and lose confidence. Conversely, if expectations are for gains in either power or status which are then realized, individuals will experience positive emotions and gain in confidence.

Phenomenological Theories

German phenomenology emphasized the search for the origins of meaning, but in the hands of sociologists like Alfred Schutz (1967[1932]), it was put on a more sociological footing by theorizing how individuals go about constructing a sense of common meanings that lead to a sense of intersubjectivity. The most prominent extension of this phenomenological thrust came from a school of theorizing and research labeled ethnomethodology (Garfinkel, 1967; Heritage, 1984; Hayashi et al., 2013), which emphasized that there are hidden 'folk methods' that individuals use to construct a sense that they share a common world and that, for the purposes of interaction, they perceive this world in the same way as others. More important than actual intersubjectivity is the perception of intersubjectivity; this perception, even if false, allows encounters to proceed smoothly and avoid breaches.

Structural and Structuralist Theorizing

The analysis of social structure has always been at the heart of sociological theorizing; and yet, there is still relatively little

consensus over just what structure is in the first place and even less consensus over its operative dynamics. Early functional theories emphasized that social structure is a system of differentiated positions in diverse types of sociocultural formations, such as encounters and groups at the more micro level, organizations and social categories at the meso level, institutional and stratification systems at the macro level, and societies as a whole and intersocietal systems at an even more macro level. Conflict theories have also conceptualized societies as differentiated but the emphasis has been on the structure of stratification systems composed of social classes and on the institutional systems that generate the inequality that ultimately causes stratification. Interactionist and other microlevel theories have emphasized the interpersonal dynamics that ultimately are the building blocks of social structure and culture, while mesolevel theories have tended to focus on status dynamics in groups and organization, and on the operation of organizations in various institutional environments. Yet, all of these conceptions of social structure, while basically correct, have not led to a more unified and integrated view of social structure and its key dynamics.

There has been a whole intellectual movement lasting almost a century labeled structuralism that, unfortunately, did not clarify social structure – if anything, just the opposite. Drawing from Durkheim's view that social structure is the number and nature of parts linked together in some identifiable pattern through which resources flow, structuralism became conflated with, first of all, the notion of deep structures that dictate the formation of observable 'surface manifestations' of these deep structures. Later, the deep structures became the neurochemistry of the human brain as it directed particular types of cultural and social structural formations (Levi-Straus, 1979). In the end, structuralism has failed at providing sociology with a clear definition of social structure, much less its dynamics.

Some like Anthony Giddens (1984) have sought to integrate at least the imagery of structuralism with microtheories by viewing structure as a set of rules and resources organized into structural principles that govern institutional formations that constrain, while also being influenced by, the agency of actors as they seek to meet fundamental needs in interactions with others. Yet, while this kind of approach makes structuralism more sociological, it does not clarify the nature and dynamics of social structures.

At the opposite end of the continuum of clarity and precision is a broader theoretical and research tradition on networks that has sought to conceptualize social structures in very precise and highly abstract terms as nodes connected in various forms by linkages or ties among the nodes, with the linkages viewed as carriers of various types of resources – information, power, affection, commitments, material goods, and virtually anything that connects individuals and the systems in which they are located. The goal of such theorizing is to conceptualize key properties of networks – number of nodes, number and density of ties among nodes, centrality of ties through particular nodes, formation of cliques of subdensities of ties in a larger network, brokerage and bridging nodes connecting networks, and the like. Depending upon the configuration of a network – from a simple network of friendships or family ties through ties among organizations in markets to ties among nation states, the form of the network is presumed to have certain dynamic properties that can be theorized – although the actual amount of theorizing has been quite negligible compared to the computer algorithms that have been developed to describe networks (rather than explain their dynamics). There is a certain clarity achieved by more precise definitions of network forms and their measurements but thus far network theorizing has not fully realized its potential as an explanatory tool that can offer a more precise analysis of social structure. Thus, whatever the future of network theorizing, it can be safely stated that it has not realized its potential (but for works that do attempt to develop theory, see Friedkin and Johnsen, 2011; Burt, 1992).

Cultural Theorizing

Cultural theorizing has many of the same problems as does theorizing about social structure: a basic lack of clarity about the key properties of the phenomenon and their operative dynamics. Culture is defined as systems of symbols carrying meanings that provide a resource for actors while at the same time carrying directives that constrain the actors; and it has been conceptualized into various types of meaning systems – the most enduring being languages, texts, knowledge systems, values, ideologies, and norms. Although these are obvious simplifications, they have been used to good effect in much sociological analysis.

More recently, a debate over the connection of culture to social structures and interpersonal behaviors has emerged, with some arguing for a 'strong program' of studying culture, per se, independent of its connection to social structure and interactions. Instead, the emphasis should be on culture in its broader historical and social context, analyzing the unique elements of culture (Alexander and Smith, 2001). This approach derides 'the weak program' that prematurely connects and subordinates the dynamics of culture to social structural and interpersonal processes, while at the same time, underplaying the unique properties of culture in order to conceptualize culture in more abstract terms.

The Weak Program

Much cultural theorizing revolves around a weak program in which theorists isolate what are viewed as key elements of culture in all social contexts, with an eye to making generalizations about the dynamics of culture in general and then trying to connect culture to generic properties of social structures and microlevel interpersonal processes. Robert Wuthnow's (1987) theory of culture meanings views culture as a system of codes and the mobilization of resources produce and sustain these codes and the ritual practices directed at these codes. Codes must reveal moral objects and programs, direct attention to individuals' real self as distinct from roles played, and distinguish between forces that are out of people's control and those that are controllable by individuals' actions. Ideologies are the most important system of cultural codes, specifying what should be, and organizing rituals affirming the ideology. The social world is viewed in ecological terms as consisting of competing

ideologies whose adherents mobilize resources and thereby seek to recruit members to their cause.

Pierre Bourdieu's distinction among various forms of capital – cultural, symbolic, social, and economic – is woven into yet another weak program that attempts to generalize about the dynamics of culture. Bourdieu's (1984) analysis of stratification represents a good example because it challenges elements of the Marxian tradition with its emphasis on dominant (upper), intermediate (middle), and dominated (lower) classes. These classes differ by the relative amounts of economic, social, symbolic, and cultural capital possessed by their members, but what makes the argument more interesting is that within each class there are 'factions' revealing varying amounts of capital. The dominant faction in all three classes always has the most economic capital for a given class, the intermediate faction has less economic capital but reasonably high levels of symbolic, cultural, and social capital, while the dominated faction within a class has the least amount of economic and often relatively high levels of only cultural capital. It is often the case that even though individuals and families are members of different classes, their relative place within a class as measure by whether they are in the dominant, intermediate, or dominated faction within their respective classes leads to cultural equivalence and hence a common identity that often makes them more comfortable around members of the same faction from different classes than members of different factions within their own class. This homology among factions dramatically changes class dynamics in a society.

There are other examples of weak programs (e.g., Fine, 2012; Turner, 2010–2013; Collins, 1975). The key characteristic of all of these programs is that they seek to isolate universal elements of culture and theorize their dynamics. In so doing, they downplay what is unique about a culture at a particular time and place and, instead, focus on what is universal about elements of culture in all times and places.

The Strong Program

The strong program argues for an emphasis on culture in its unique context. However, when seeking to theorize cultural times, many strong programs are transformed into weak ones because of the effort to isolate generic properties of culture and theorize their dynamics. Jeffrey Alexander (2004), for instance, has been among a group of scholars advocating a strong program, but in his own theoretical statement on cultural pragmatics, Alexander converts his more descriptive works into a weak program, which may be necessary if theory rather than description of culture is the goal. His main idea is that as societies become more complex and differentiated, a disconnect emerges between the texts, background representations, and scripts of culture (as described in the strong program) and the ritual performances of actors in front of audiences; and this disconnection often makes actions and performances seem artificial and strained. Thus, successful performances by actors involve re-fusing performances so that they decode culture and arouse emotions in the audience, thereby pulling individuals into culture in its more robust forms.

Whether a weak or strong program, it is clear that cultural theorizing has accelerated over the last two decades in sociology. Partly as a reaction against conflict theories that often portrayed culture as a 'superstructure' or adjunct to material conditions and social structures, theorists have shifted to emphasizing culture as a force in its own right. Both the weak and strong programs emphasize that the dynamics of interpersonal behaviors and social structures cannot be understood unless theories on the properties and dynamics of culture as force in their own right are first developed.

Critical Theorizing

Since its beginnings, sociology has devoted much theorizing to the problems of modernity. Whether Marx's analysis of alienation and exploitation, Weber's negative portrayal of rationalization, Durkheim's analysis of anomie, Simmel's analysis of marginality and other pathologies of differentiation, and modernity, sociology has always been a critical discipline. Some theorists have sought to remain value-free even as they offered criticisms of problematic conditions; others have remained explicitly normative, advocating for changes in those patterns of social organization viewed as oppressive and harmful to humans.

Critical theories in the mid- to late twentieth century became not only critical of social conditions but also of the scientific pretensions that sociological knowledge can solve these problems; and thus critical theory is critical of both society and science, which is often seen as part of the problem.

The Frankfurt School

Early critical theorizing began in the 1930s in Europe among a group of scholars in the Frankfurt School, even though some were not German or even based in Frankfurt. The basic problem they confronted was that Marx's emancipatory dream seemed dead as fascism spread across Europe in the build up to World War II. Indeed, Weber's view of social life as increasingly caged in a steel enclosure of rational-legal domination by the state and spread of bureaucracy seemed to be a better description of trends, leading scholars to ask: How is emancipation from such rational-legal domination to be achieved? The answer to this question became highly philosophical but, in essence, a variety of scholars from Gyorgy Lukacs, Max Horkheimer, Theodor Adorno, Antonio Gramsci, Louis Althusser, or others emphasized that, while transformative change may not be possible in the present, it was important to expose and analyze patterns of oppression and to propose possible solutions, even if change itself was not possible at this point in history. Later, under the intellectual leadership of Jurgen Habermas (1981–1984), (1973[1976]), the Frankfurt School of critical theory began to emphasize, again in a highly philosophical way, that the public sphere of the eighteenth century where ideas were once debated without recourse to dogma needs to be reconstructed in the modern world. Habermas proposes that the goal must be to move toward what he saw as 'the idea speech act,' composed of three main elements or implicit assertions that acts are the most effective means to ends, are correct and proper in accordance with relevant norms, and are sincere as well as authentic. If social conditions can increase the production of such acts, the public sphere can

be recreated, and solutions to the problem of invasion of the lifeworld or culture by the material forces of production and state management can be overcome. A new kind of communicative rationality can emerge, which can weaken the means-end rationality that has dominated modern societies.

Postmodern Critical Theories

For two decades, many sociological theorists were positing a new stage of societal evolution: the postmodern. Like modernists theorists, they emphasized that the new postmodern condition reveals structures and cultural forms that are harmful and pathological, and at the same time, they have been equally hostile to science as presenting solutions to these pathologies. Science presumes to offer 'a grand narrative' about the dynamics of the social world, but this narrative should not enjoy a privileged position. Moreover, the era of grand narratives needs to come to an end, which is somewhat ironical because postmodernism has proposed its own grand narrative. This narrative has two variants: economic and cultural.

Economic postmodernism emphasizes the pathologies generated by overaccumulation of capital and its rapid movement around the globe (Harvey, 1989; Jameson, 1992; Lash and Urry, 1994). Such movement has a number of harmful effects, including reducing the price of labor and hence income from work all over the world; increased financial speculation in meta markets that often collapse and cause longer term economic dislocation; decreases in the power of national governments to control their money supply; and decreasing capacity of government to control capitalists and key economic actors bent on self-interest rather than collective interests of people. Coupled with cultural changes arising from the overproduction of technologies of reproduction (i.e., media images detached from empirical reality), many new pathologies for humans and societies emerge.

Cultural postmodernists emphasize the spread of technologies of reproduction through media images and the increasing detachment of culture from its origins as it is marketed as a commodity (Baudrillard, 1994; Gergen, 1991). When culture is detached from its material base and becomes a commodity, it is trivialized and becomes a free-floating bundle of symbols that can be tried on for appearance and then easily discarded. This process is accelerated by the prominence of cultural images, as they spread around the globe via many sources of media reproduction. The result is that symbols have ever-decreasing meaning and capacity to provide anchorage for self and identity. Images can be acquired via media and/or purchased as a commodity in markets, tried on for their transitory effect, and then abandoned. The result is that individuals become over-reflexive about self, while at the same time incapable of forming stable identities that give their actions coherence and meaning.

Postmodernist theory has been in decline now for about a decade because some of its claims seem excessive, without clear empirical support; and since postmodernists rejected the epistemology of science, they would not accept tests of their theoretical assertions as useful. Yet, there can be no doubt that both variants are denoting important sociocultural changes, but whether or not they represent something new remains open to debate.

American-Style Critical Theories

In the United States, sociology has always had a critical slant. The first American sociologists all pledged allegiance to science, but only a few had any training in science and most were concerned with amelioration in the post–Civil War era. Contemporary American critical theorizing is almost always normative, suspicious of the claims of science, and concerned with exposing and eradicating oppressive social conditions experienced by ethnic minorities, later with the oppression of women, and more recently with the question of gays, lesbians, and increasingly transsexuals. These issues all became part of civil rights movements and then the ideologies and concerns of these movements were absorbed into departments and programs in American academia where the ideological zeal remains but is supplemented by more academic analysis, most of which has been suspicious of science. The result has been a mix of historical description, philosophical discourse, outright advocacy, and activism. Much of this American style critical theorizing is not really very theoretical, but some of it is, in the broader sense of 'social theory.' Feminism is now the most active critical approach; although ethnic relations remain a strong theoretical concern, they are spread among both those committed to science in sociology departments and those more concerned with activism in various types of ethnic studies departments and programs. GLBT issues can also be found in women's studies departments, and even a few programs explicitly devoted to these questions, as well as older, established departments such as English and History programs in the United States (for summaries, see Turner and Turner, 2013).

The State of Sociological Theory

Today, sociological theorizing is a very broad enterprise, and the review here can only touch upon the range of theoretical approaches. There are many variants of theory within any of the main approaches outlined in this article, but the main contours of theory today are at least clear. Since theory in sociology must examine all of social reality, from its micro- through meso- to macrolevels of reality, it inevitably must be a very broad subject area. Many of the structures operating at various levels are, of course, subject areas in their own right, as can be seen by other articles in this encyclopedia, but it is theorizing that brings them together more than any other subdiscipline within sociology. Yet, the barriers created by specialization – indeed, overspecialization – in sociology represent one roadblock to more comprehensive theories. Another, more fundamental roadblock is that many who consider themselves theorists do not consider scientific theory as possible, or even desirable. Thus, this epistemological split assures that theory will remain rather spread out and chaotic. Such has been the nature of sociology from its beginnings, and if anything, the split between science and its skeptics is greater than ever in the second decade of the twentieth century.

This article is a revision of the previous edition article by E.A. Tiryakian, volume 23, pp. 15824–15829, © 2001, Elsevier Ltd.

Abstract

Scholarly work in sociology in different places and at different times is guided (often simultaneously or sequentially) by a variety of traditions that take different forms (e.g., sometimes in quite formal 'schools') and emphasize different aspects of scholarly activity (metatheoretical, theoretical, methodological, ideological, etc.) and that rise and fall according to a range of societal, scholarly, and other conditions. Often, such traditions are national or regional, or at the very least are shaped by national or regional contexts. Apart from providing an analytical framework for understanding the role of traditions in sociology, this article also explores the broad course of historical developments of some major traditions.

The Importance of Traditions

Almost inevitably, sociologists' decisions are strongly, albeit often unconsciously, influenced at each point in their projects by received or developing traditions, paradigms, and lines of thought and are socially influenced by the 'social embedding' of such cognitive structures in 'schools,' 'theory groups,' 'research networks,' and other forms of intellectual social organization, some organized along national lines. Many sociologists would argue for the importance of traditions as providing the continuing backbone of sociological thinking, and are prepared to invest energies in their maintenance and communication, and often in debating the merits of alternatives. This is so particularly in the teaching activities of sociologists in which appropriate typologies are constructed and reconstructed.

As Levine (1995: p. 13) has remarked, sociology was officially born carrying with it a schema of its own history: for example, Comte coined the term and simultaneously laid out his version of its trajectory. Yet it seems strange that the very discipline whose business it is to pry into the affairs of other groups knows so little about itself that there is only very scattered data on its membership, their interests, and their theoretical and methodological positions. There is much debate about theory and types of sociology, but little knowledge of what views are held by the vast majority of workaday sociologists who presumably comprise the audience for these debates.

There is a considerable range of views about the nature and scope of traditions, which change over time and across national and other social contexts. Moreover, it is unclear what the extent of consciousness is among traditions, and the degree to which sociologists are able to follow through with proclaimed choices. Some sociologists clearly cleave to a particular approach, but at the other extreme, some deny being influenced by any specific tradition.

Much more has been written about national or regional sociologies. Several volumes have been collated, which include country-by-country accounts, although not usually country-by-country comparisons (these include several 'World Handbooks' with country chapters, e.g., Mohan and Wilke, 1994). There seem to be many claims to regional or country traditions, but not too many of these seem to survive closer examination. Many national sociologies follow similar trajectories. As with the overall trajectory of sociology, many countries did include in their prehistories of sociology particular figures who loomed over later sociological developments and who by projecting their particular scholarly idiosyncrasies bequeathed a particular national flavor to the sociology of their country. Such scholars may have been jurists, literary or philosophical theorists, or more generic social scientists. However, such national traditions tended to have short lives. In the postwar period, sociology worldwide was invaded by American sociology with its empiricism (symbolized by survey research and a 'scientific' approach) and structural–functional theory. However, by the 1970s, other traditions percolated out from the first world core of sociology to challenge the hegemony of the American approach: especially various macro- and microsociologies. This widening of perspectives, too, allowed room for the development of national traditions. But most national sociologies are probably best characterized as particular 'mixes' of the then current metropolitan (and therefore world) sociological traditions. Nevertheless, such local versions of the world tradition often have a local, national, or regional 'flavor.'

Conceptualizing Traditions

The term 'tradition' emphasizes rather too much the connotation of respect for past thinking. But 'school' implies rather too much a formal organization, leadership, and even intellectual control from a leader (or leaders). The ambiguities around Kuhn's (1970/1962) fecund term 'paradigm' have led to a major commentary industry. Here, the term 'national sociological tradition' refers to any cognitive formation organized along national lines that lends consistency to aspects of thinking among sociologists, whether the doctrine concerned is unique within sociology or is also shared by wider groupings of intellectuals or scientists.

Donald Levine (1995) has provided a useful imagery of what lies at the heart of any sustained and cumulative sociological discourse. He sees each tradition as a conversation, a dialogue between networks of sociologists who tend to share particular assumptions about social reality. Since, as with other largely text-based intellectual activities, time and space are limited as Barriers conversations can readily be held across as well as within generations and across countries (as well as within them). Levine defines traditions as inter- and intragenerational

conversations amongst scholars. The uniqueness of any tradition must usually be placed within the context of the other traditions then pertaining, and on the relations among these traditions. Usually, contemporaneous traditions are in competition, and sometimes in conflict, although they may also ignore each other.

There is a tendency among historians of social theory to restrict their concerns to traditions that are theoretical. But sociological work (and thus any fully formed tradition) must inevitably cover, at least, each of metamethodological, conceptual, methodological, data, and ideological aspects, including interrelating with the general population. In terms of their internal state, traditions may vary in terms of their degree of historical development, the tightness of their formal development, the tightness of fit of the linkages between the theory espoused and the facts considered important in the tradition, the closure of their boundaries, the degree of reflexive consciousness with which they are held by adherents, the moral tone that is pursued, etc. In his study of types of sociology, Menzies usefully distinguishes between 'theorist's theory' and 'researcher's theory,' which have different characteristics. Further, as Schumpeter pointed out, some of these schools are 'virtual' being merely groupings of writing, whereas some are real: based on ongoing social activities among its members (albeit at a distance). In addition, at least for socially real traditions, there are more social aspects to traditions that may also affect their trajectory: the degree of social cohesion, organizational contours, shared cultural assumptions of adherents, etc., and their fit with the environing culture and society.

The several aspects of a tradition can more formally be classified into the following:

Levels/ dimensions	*Substantive*	*Methodological*	*Moral*
Ideas	Concepts, theories, etc.	Methodology, assumptions, etc.	Moral vision
Facts	Findings, empirical generalizations, recommendations, etc.	Methods	Practical

Important writings in the (historical) sociology of sociology have drawn attention to each of these major dimensions, for example:

- Kuhn: the importance of underlying conceptual assumptions and models, and the intellectual community upholding the 'paradigm.'
- Gouldner: the importance of underlying conceptual assumptions and models, and the grounding of views in personal experiences.
- Freidrichs: the importance of the underlying moral views.
- Platt: importance of traditions of social research methodology.
- Levine: the importance of the type of 'organizing model' (narrative) about the trajectory of sociological development held by the historian.
- Burawoy: public, academic (professional), and critical approaches.

Classifications of theory are not only part and parcel of normal sociological argumentation but also are developed by those textbook writers whose contribution it is to provide classifications and histories of theories. Such classifications then tend to become built into classroom teaching, especially in theory (often taught as history of theory) and history of sociology courses, and begin to take on a life of their own. The validity of such classifications is often not tested.

Stephen Cole (1992) has drawn attention to the difference between the 'core' and the research front. He suggests that the cognitive structure of most sciences consists in a few theories and procedures over which there is complete consensus and which can be readily presented in textbooks, and a 'research front' marked by minimal consensus and much diversity of approaches, methods, and models. Another conception is that there is a 'world' of textbook sociology that has a life of its own, with often a minimal connectivity to the research front. Traditions may live rather different lives in each of these two different worlds.

As in other disciplines, there is international interest in how sociology is progressing in various parts of the world and several (edited) volumes have been constructed at fairly regular intervals that carry this out using a national frame of reference. However, neither the assumptions of national differences inherent in such an approach nor the reliability of judgments about national peculiarities drawn by observers is adequately tackled.

Traditions may have trajectories. Onto Kuhn's schema, which contrasted periods of 'normal science' and 'revolutionary periods,' philosophers of science have grafted other terms such as 'progressive and regressive shifts,' which spell out the progressions in more detail. Sociologists have also developed 'phase models' of the development of specialties – which might also apply to sociological traditions (cf Crane, 1972; Mullins, 1973; Rule, 1997). Traditions and specialties are often built on a slowly developed platform, and then break away into a fast-developing growth phase, before hitting a plateau and in some cases then declining. Institutionalization, and obtaining a secure supply of requisite resources and recruits, is necessary for a tradition to be sustained (cf Turner and Turner, 1990). Traditions often forge strong social ties among members, with master–apprenticeship relations being essential for their longer term growth (cf Mullins, 1973; Collins, 1994).

Alexander and Colomy (1992) have developed a terminology for charting the complex 'progress' of a tradition, which includes

- Elaboration (i.e., refinement), proliferation (extension of scope), and revisions (relating back to the core) as three lines of specification.
- Reconstruction, which involves acknowledging differences with the founder and openings to other traditions.
- Tradition creation: "The essence of tradition-creation is the synthesis of elements drawn from several existing and often competing intellectual paradigms, with the aim of generating the theoretical core of a new school" (p. 37). Alexander has argued that over time particular strategic cognitive patterns are likely to emerge, with disciples, for example, tending to soften the particularities that the tradition's masters tended to emphasize. Mulkay develops

a more radical argument whereby "Theoretical development is regarded as being neither continuous nor, in any direct way, cumulative. Instead, it is seen as arising from a number of discrete and intermittent theoretical reorganisations, which centre upon new strategies devised as replacements for the unsuccessful policies adopted by prior theory" (1971: p. 3).

Predisciplinary National Traditions of Social Theory

Levine argues that more light is thrown on the development of sociological thought by endeavoring to grasp the national channels in which it flowed for some centuries. Levine's schema builds on the (often binary) classifications of traditions set out by other writers, but pursues a more detailed examination. He "… define[s] them primarily as national traditions, for two reasons. The originative figures of modern sociology mainly cite fellow nationals, as, for example, Halbwachs is likely to cite Rousseau; von Weise, Simmel; Park, Sumner. More important, over the generations they reproduce what are palpably national characteristics. Moreover, when they engage in dialogue with parties from other national traditions, they do so, openly or by implication, in a more contrastive mode – as when Durkheim explicitly contrasts his French discipline with British and German traditions" (1995: pp. 99, 100). A national tradition then tends to submerge within a more universalistic discourse.

Each national culture tends to make similar ontological assumptions about the nature of social reality, and how it might be known (Levine, 1995). These assumptions underpin social science work in that country, and these views often have been articulated by important philosophers – who then act as something of a 'skirmish line' clearing the way for, and shaping, later sociological thought. In particular, cultural choices tend to be made between stressing the individual level as ontologically prior (as in the United Kingdom), or the collective level (France), and between an objective approach (as in both the United Kingdom and France) compared to a more subjective approach (as in Germany). Although there is a long-term consistency in the development of these approaches, there can be considerable variation within them, and they are often formed in part through a conversation with other theoretical traditions.

Levine identifies the various national traditions in sociology as follows:

- Aristotle, representing the Hellenic tradition, is concerned with the way in which different constitutional arrangements of societies (city states) shape the conditions for achieving human virtues, and thus human happiness, with the achievement of that potential arising from the deliberative judgments of the participants.
- The British tradition emphasizes the naturally sociable disposition of individual humans: for example, their preoccupation with the properties, rights, liberties, and utilities of individual actors, and then the conduct of the actors.
- The French tradition emphasized that "… society formed a supra-personal entity with properties and needs of its own, above all needs for normative regulation and solidaristic integration" and that it was a natural phenomenon.
- The German tradition emphasized human freedom as an essential element of moral decision making, and also affirmed the creative power of language as a distinctive feature of human action and morality.
- The transnational Marxian tradition emphasized elements elicited through critique of several of the other traditions in order to combine, in his final synthesis "… Kant's notion of self-determination, Hegel's notions of collective historical development, French notions of associated humanity and social classes and the British conception of the competitive pursuit of individual interests in the marketplace" (p. 222).
- The Italian tradition sought laws about societies as natural systems with the prominent features of these systems being the functioning of ruling classes or elites.
- American pragmatism stressed social activism disposed to solve problems on an experimental common sense basis.

Although the attention of historians of sociology is particularly drawn to examining theoretical traditions, there are also research traditions (or more broadly methodological traditions) that may not at all be strongly linked with the more theoretical traditions. The State, as the key institution in developing statistical information, is particularly important in shaping the types of empirical research and methodological developments that eventuate in a particular country.

Undoubtedly, the most important methodological breakthrough in the social sciences was the German historian's concerns with methods for validating the reliability of documents. This led to a more widespread tide of heightened methodological standards. In addition, Levine (1995: p. 276) suggests that "The empirical traditions also bore the mark of national dispositions, if not in such a pronounced from as the philosophical ones. England led the way with social surveys, systematic investigations of living and working conditions, mainly of members of the working class. France and Italy pursued the collection of national social statistics, work that enabled Durkheim to lead off so impressively with his analysis of divorce rates, educational levels, mental illness data, religious affiliation and the like in Suicide. Germany pioneered the experimental manipulation of subjects and also the systematic collection of ethnographic data in broadly defined culture areas. The US pioneered in producing census data and later in systematic gathering of information through personal documents and direct observation as well as interviews."

There has been relatively little recognition of these broader (philosophical) traditions of thinking that influence how sociological work is carried out. One theme has been that of positivism, which has been deployed by many more specific sociological traditions. Bryant usefully points out that positivism has cycled through several variants, including the French version of Comte and later, Durkheim, and the Austrian approach, before being developed with rather different emphases in its more modern form in the United States over the last century. Another theme that has attracted much discussion is the Marxian approach, which seemed to peak in the 1970s. This approach was often quite visible and self-conscious – even sometimes setting itself outside the normal boundaries of bourgeois sociology. Several writers (e.g., Giddens) have struggled to identify a postpositivist philosophical mood.

Midcentury US Sociological Traditions

However, these various European traditions tended not to be well institutionalized, with slender holds on university positions, and these faltered after World War 1 undermined several national groupings. The United States then became the setting in which earlier sociological traditions were selectively retained, and further sociological traditions unfolded.

In the mid-1930s, Talcott Parsons endeavored to establish a more solid cognitive base on which future social theory might be built through consideration of a mix of theorists (each perhaps representing different traditions, although it is not a point in Parsons's argumentation), which he argued shared common features critical of utilitarian doctrines and instead positing a more sophisticated 'theory of action': Marshall, Pareto, Durkheim, and Weber (with suppressed attention also to Simmel and to Marx). By the immediate post–World War 2 (WW2) period, this synthesis was broadly accepted, even if its particular manifestation in his writings was not. This gathering emphasis on theory was reinforced by many refugee social theorists who had migrated from Europe.

This theoretical synthesis extended into a sociological functionalism (or structural functionalism) is seen as the major approach that dominated sociological discourse in the 1950s and the 1960s, beginning earlier than this and certainly carrying on at least into the 1970s. Alongside this approach was the 'loyal opposition' of symbolic interactionists mainly concerned with microsociological processes. However, with the social upheavals and movements of the late 1960s and certainly during the 1970s, the hegemony of structuralism was seen as being challenged from below and above. Microsociologies became more fashionable, but so too did macrosociologies with (Weberian) comparative/historical and more radical Marxist approaches becoming more prominent (with a milder version lying in a postulated dichotomy between consensus and conflict sociologies).

On the methodological side, content analysis was developed, especially in the context of WW2 and the Cold War when direct access to totalitarian countries was denied and more indirect means of study were especially required. As consumer choices became more important and with the spread of advertising to media such as radio where the audience was not readily identified, survey research became increasing important as a method and was increasingly institutionalized. It enabled the scale of study to be extended from communities to nations (and later across the world). Surveys became inextricably linked for many sociologists as the landmark methodology of their discipline. The methodological emphasis of US social science, flowing from a broadly 'positivist' philosophical orientation, led to the very considerable systematization of social research methods there in the mid-nineteenth century and this led to the establishment of a tradition of social research methods texts that codified methodological knowledge. Moreover, this established American sociology then was actively exported around the world as a model for pursuing sociology.

However, closer examination of available content analyses of the published sociological literature shows that while functionalism was strongly established in the textbook literature, it failed to penetrate far into the research front of sociology. The many meanings of functionalism confuse the picture, and in particular diverted attention from the structuralism which underlay so much theoretical analysis and empirical research in this period and subsequently.

Contemporary Sociological Traditions

In the past quarter century, a much wider range of theoretical material has been incorporated into sociological theory, and the role of continental and British theorists has become far more prominent. However, the reception of such theories in other countries can be quite different to that accorded them in their home country: for example, some of the more successful French theorists have occupied marginal academic positions in France but have been accorded much emulation in Anglo–Saxon countries.

Sociological traditions were rewoven in the England-domiciled work of Giddens, a recent theorist sensitive to a wide range of traditions of sociology. Giddens began with a series of essays taking into account each of the received traditions mentioned earlier in this section, largely criticizing their deficiencies and also winnowing out the useful residue that might be reclaimed from their work: he began reviewing the received traditions (functionalism, materialism) but then examined a wide swathe of traditions in order to recruit appropriate ideas for sociology (including ethnomethodology, hermeneutics, and poststructuralism). The useful material he assembled was then incorporated in his own 'structuration theory.' In France, Bourdieu accomplished a similar synthesis with its own unique features and a better connection with social research work.

Consequently, by the 1980s, a considerable agenda of approaches was on the table: one stream emphasized Marxian approaches and more generally political economy, or conflict sociology. There was a rising tide of 'subjectivism' and focus on the individual social actor. In their useful summative presentation, Giddens and Turner suggest (problematically) that the changes were largely driven by a revised underlying philosophy of science imbibed by sociologists:

> Over the past two decades, however, a dramatic change has occurred. … developments in the philosophy of natural science have inevitably influenced thinking about the social sciences, while accelerating an increasing disillusionment with the dominant theories of 'mainstream social science.' The result of such changes has been a proliferation of approaches in theoretical thinking. Traditions of thought that previously had been either little known or ignored have become much more prominent: phenomenology, particularly associated with the writings of Alfred Schutz; hermeneutics, as developed in the work of such authors as Gadamer and Ricoeur; and critical theory, as represented by the works of Habermas. Moreover, older traditions of thought, such as symbolic interactionism in the United States and structuralism or post-structuralism in Europe, have more recently developed types of thinking, including ethnomethodology, structuration theory, and the 'theory of practise' associated in particular with Bourdieu. … There continues to be something of a 'mainstream', even if it is navigated by fewer than before. Parsonian structural-functionalism, for example, still exerts a strong appeal and, in fact, has undergone a considerable revival recently in the writings of Luhmann, Munch, Alexander, Hayes and others. (Giddens and Turner, 1988: pp. 2–3)

Just as this agenda of different traditions had become well established, especially within American sociology, a further wave of social thinkers came to the fore in European sociology. Whereas the earlier wave of groupings operated under doctrinal titles, albeit closely linked with particular key figures, the new round of thinkers were more individualistic. Some of the major figures clearly included Foucault, Derrida, Giddens, and Bourdieu. While some attempts have subsequently been made to name and classify the approaches adopted by these later-day theoretical saints, such classificatory bundlings have, however, been fiercely resisted by their protagonists. Over the past two decades, two rather more broad approaches also gained considerable notoriety and influence – although their demise has since begun – poststructuralism and postmodernism.

National Subtraditions

Besides social science–wide or discipline-wide traditions shared by sociologists, some traditions are specific to particular specialties. For example, addressing the specialty area of the sociology of science, Zuckerman (1988: p. 512) comments that there are not only different viewpoints but also that she sees (p. 513) these differences in views held within the specialty as flowing from national perspectives, especially between the United States as opposed to UK/European sociologists of science. With many exceptions, the North American approach tends to be more research orientated, functionalist, and 'positivist,' whereas the European approach is characterized as more comparative/historical and 'critical.' Other specialty areas offer other nationally specific patterns (e.g., see the chapters in Quah and Sales, 2000).

From time to time particular specialties seem of prime importance as pace setters at the cutting edge in setting traditions, and these may reflect national emphases. For example, in the 1960s, the 'new criminology' emphasized the application of symbolic interactionist and also Marxist approaches to the sociology of deviance, and this had broader implications for sociology as a whole. Another specialty area that has been of importance is that of social stratification, which has been a particularly contested area in which competing sociological traditions have been challenged to exhibit their causal efficacy.

Among genuine regional sociologies, the outstanding example is the dependency school of Latin American social scientists, although it is as much claimed by economics as by sociology.

For example, in the development period of functional analysis, one of its key contributions was in the area of stratification with the notion that stratificational orders were of functional consequence for their societies by motivating the filling of key societal roles by people with higher skills and ambitions since incumbents of such positions were rewarded by higher social and economic rewards.

Cross-National Integration of Traditions

Intratradition conversations usually allow fine-tuning of differences, whereas intertradition debate can be a major influence on the development of national traditions. Levine places particular emphasis, for example, on the way "the divergent postulates that underlie … persisting differences were honed and deepened in the course of centuries of mutual confrontations between British and French social theorists" (1995: p. 173). He then briefly sketches interactions involving Montesquieu against Hobbes, Rousseau against Hobbes, Smith against Quesnay, Comte against Smith, Mill against Comte, Spencer against Comte, Durkheim against Mill, and Durkheim against Spencer. More generally, Levine discusses links amongst German, French, Italian, British, and Marxian traditions. The structure of such intergeneration interactions is largely determined by the differential start times of each of the national traditions, which broadly has the pattern of British, French, German, Marxist, Italian, and American. Some patterns of 'alliance' can be seen in which some groupings of national traditions band together against others, while sharing internal differences. In particular, Levine sees "The formidable German defence of subject-orientated assumptions against Anglo-French support for naturalistic assumptions… [as originating] … one of the persistent fault lines in modern social science. Such dialogues can be effective in sharpening differences, as much as they lead to exploration of commonalities."

Transnational Contexts

There are several mechanisms through which national traditions are transcended: especially through international scientific associations and conferences. These can be at different levels of scientific intensity – merely diplomatic exchange to joint attention to scientific issues. International gatherings can be an arena for parading (and even exacerbating) differences or attempting to meld and conconstruct. The United Nations Educational, Scientific and Cultural Organization–supported International Sociological Association was a major sponsor of several national sociologies and perhaps this support carried with it the seeds of particular approaches to sociology.

However, forces conspire to keep traditions separate from each other. One mechanism is sheer mutual ignorance. The classic example undoubtedly is of the mutual unawareness of Durkheim and Weber – two giants of sociology working at exactly the same period and separated by only a few hundred kilometers of physical distance, although perhaps sheltered behind two only partly open national contexts. Another puzzle has been how long it took statistical methods appropriate to social data to emerge. Statistical methods were (famously) largely innovated in late Victorian England at a time when there was much social research, but measures such as the correlation coefficient were only pressed into sociological service (at Columbia University by Giddings in particular, see Camic and Xie, 1994) a bit later and on the other side of the Atlantic. In a long and almost despairing essay, Goldthorpe (2000) traces the failure of probabilistic statistical treatments of social phenomena to match with rational choice theory. In each of the main national traditions, the possibilities loomed but were never consummated. While organizational reasons did limit the linkage, intellectual barriers were more significant.

In some situations, rewards flow from establishing difference rather than trying to advance sociology cumulatively by carefully building on the work of others. In Lemert's portrayal of the French intellectual scene, for example, he argues that the intense competition for the spotlight encourages the celebration of difference, and underplays the constructive engagement between attentive sociological viewpoints to confront and perhaps reconcile overt differences. Indeed, Lemert argues, appropriate 'rivals' are not even explicitly named as audiences are sure to pick up subtle references.

Rivalry between traditions is often 'social': driven by interests in acquiring resources, recruiting bright students, and catching the attention of policy makers, funders, or the intelligentsia more generally. For example, the 1960s' rivalry between Chicago, Columbia, and Harvard was not necessarily combative but, nevertheless, was underlined by snideness and stereotyping.

The Shaping of Traditions: A Comparative/Historical Account of Factors Shaping Traditions

The rise and fall of (national and other) traditions are shaped by various cultural, ideological, political, institutional, cognitive, and social factors both generally and also in different ways in different national contexts. Such external influences may override some of the internal dynamics of traditions (which are often international).

The broadest influence flows from culture. Cultures stressing the importance, in both the natural and social realms, of the acquisition of rational explicit scientific principles and of empirical fact finding, and even more importantly the importance of developing systematic ways of interfacing the rational and the empirical, are much more likely to foster successful social science. An important influence on the development of social science is the model of natural scientific inquiry admired in that nation by its social scientists. Each of the main traditions defers to philosophers, and also scientists of more general importance, whose understandings of science were highly consequential for work in that tradition. For example, Newton's views on science had a particular resonance within subsequent British thinking.

Aspects of religious thinking in a country also affect the development of science and social science. Prior to the reformation and enlightenment, secular social thinking was often discouraged. Moreover, "In Protestant countries close relations developed between intellectuals and churches. Intellectuals were harnessed in the conflict with Catholic ideas and politics; there was more room for debate since (some) Protestant religions were not anchored by a central dogma; and since Protestant clergymen could raise families, intellectual dynasties could be more readily formed. Thus, in England, and also the Netherlands and Scandinavia, scientific innovation was linked with religious debate. However, in France secularisation of intellectual culture took place with support from the state and the court, and did not involve the development of scientific thought, since literary genres were dominant. Therefore scientization without secularisation in contrast to secularisation without scientization" (Heilbron, 1995: pp. 63–64).

Different cultures house much the same range of ideological perspectives, but some national consistencies can be found. French ideology more often stresses radical change, drawing on its rationalist heritage, whereas in the United Kingdom and the United States, emphasis is more on piecemeal reform, flowing from a strain toward empiricism. In Germany, ideology is often idealist, humanist, and antipositivist.

Each culture has somewhat different ways of portraying what is covered within the realm of the social sciences and what boundaries are set. In Germany, *sozialwissenschaften* is a broad conceptualization, whereas in the Anglo–US world, a sharper distinction is usually drawn between the social sciences and the humanities. France is more complex, with economics located within Faculties of Law, whereas the other human sciences were located within the broader humanistic framework of Faculties of Letters. Which particular disciplines are separately identified has also differed, with some continental university systems often presenting more 'policy-orientated' types of knowledge; for example, demography, criminology, and sociography in the Netherlands. More recently, the distribution of disciplines that developed in American universities has successfully diffused worldwide, and has become the norm against which the array of disciplines in other countries came to be measured. The main disciplines of social science, including sociology, tend now to have an American imprimatur. However, even if the general approach of the discipline has been set by its grounding in American institutional structures, the content of sociology has more recently been more often influenced by continental sources (and especially French-based social theory).

Each culture understands the relationships between its component 'social fields' rather differently. Although most modern societies have in common separate economic, political, and social realms, together with many minor arenas of social life (e.g., Legal systems), how each is constituted and what its relationships are to other spheres may differ considerably, and this has consequences for social science work in that society. The various disciplines tend to have a particular interactive relationship with one or other of the social realms in that society, with the social science discourse being in part 'constitutive' of that realm, and in part being shaped by it. These schema constitute 'deep structures' that may implicitly guide the development of particular national traditions over many generations. For example, in France, the state has long been a very central and powerful institution, although there has been a strong discouragement of scholarship in political science. In France, society ('the social') became distinct from church and politics, and then the economy, but in Germany, the distinction was resisted. The possibilities of the development of sociology were shaped by these differences.

There is also a link between national sociologies and their colonially linked sociologies: so that, for example, British or French influences shape the nascent sociologies of a range of other (excolony or influenced) countries.

Regional sociologies often stand behind national sociologies – either explicitly or not – and although geographical contiguity is often involved, common language can be even more powerful. Latin American sociologies have many similarities, and in contemporary Europe, considerable effort

is being put into constructing and critiquing the development of regionally based sociological viewpoints.

During the period of German university development from the late 1700s through the mid-1800s, literary and artistic intellectuals were not accommodated in universities. One result of this appears to have been "the independent non-university intellectuals became hostile to the new professorial form of knowledge production" (Heilbron, 1995: p. 24). This involved a Romanticist rejection of cold hard facts, which developed alongside, and in reaction to, the professionalization of knowledge, and provided an alternative and oppositional stock of intellectual resources, which has most recently been drawn on in the development of postmodernism.

The policy process is different in different states. In the United Kingdom, fact finding was institutionalized in the role of Royal Commissions, inspectorates, and social reform research associations, but these were weakly linked (at least as far as formal ties are concerned) with the policy making. Social network ties among various members of the elite could provide channels for information to percolate to policy makers. However, links between social researchers and policy makers have remained ever since generally at arm's length. In Germany, there was also considerable state involvement in statistics collection. On the other hand, in the Netherlands, a tradition of longer term policy making developed and this was able to articulate with a slew of empirically orientated research approaches such as sociography and social geography, which were particularly well developed there. The interest of states in social research and their capacity to promote it and then to utilize findings varies considerably.

Besides the state itself, social sciences traditions may be shaped through interaction with a range of coalition partners, including scholarly and/or professional organizations of social scientists, the social science–based semiprofessions, and a wider array of social movement organizations. In many countries, there has been a development of semiprofessions, at least partly based on sociological knowledge (social workers, planners, nurses, librarians, psychologists, economists, educators, and teachers), and their differential association with sociology has affected the development of national traditions.

A range of coalition partners, which differ in particular circumstances, may shore up the development of social science knowledge, especially where there is a cognitive and moral affinity. Such partners may include political parties, trade unions, probusiness groupings, welfare reform groups, or more generally, social movements. Often, some aspects of sociology relate to these in terms of some 'discursive affinity,' an overlapping of key concerns, and some basic similarity in cognitive assumptions and terms. In such circumstances, the sociological work provides some of the conceptual elaboration and/or the social information required to support the program of its ally, while the ally may assist in providing treatments of what issues are problematic, in providing empirical material (e.g., access to research sites), and in mobilizing resource support, plus providing a more general legitimacy. This relationship is often strengthened when the partner obtains parliamentary power or is in government. More recently, think tanks have been set up to mobilize social science knowledge for more specifically ideological purposes, especially in support of the doctrines of neoliberalism. Supporting social movements are often especially important in the internationally linking of national traditions; for example, Marx bequeathed his writings to the German socialist movement (which gained a parliamentary foothold in the 1880s and the 1890s), which harbored them to display for widespread trade union and academic utilization at the turn of century.

The effects of different institutional forms and the material basis of the provision of resources have been especially important for fueling the differential development of sociology. A range of institutional forms have been relevant in different times and places: coffee houses, salons, associations, university teaching departments, and research institutes (cf Coser, 1965). Salons and coffee houses can be significant for the flexible innovation of new ideas. Universities can be important for providing a more secure and longer staying environment, with systematization required for teaching and some degree of system rational allowed and pushed for. University settings propel specialization, and divisions of labor, especially in the form of formal development of separate disciplines. However, university teaching departments are not necessarily appropriate institutions to support larger scale research so that the tackling of larger topics, and also policy research, often requires the development of research centers where a specialized division of labor can be built up and resources for particular products mobilized.

Different national university systems have provided different contexts for the development of sociology. The German universities were reformed from the 1820s on and launched a range of more systematically based scientific work, especially in philology and then extending especially into history, which was placed on a far more scientific footing. The French system, which was not revivified until the 1870s was (and still is) highly centralized, which can mean the rapid institutionalization of a particular area of knowledge, although the centralization can prove intellectually stultifying. As with natural science, the American university system in which presidents have strong power to develop new areas, where there can be fierce competition for prestige among institutions, and where (at least in larger universities) the appointment of several full professors in each department fosters a democratic climate and a diversity of lines of research, seems to have been a particularly successful environment within which social science, including sociology, has flourished. The timing of reform to university systems seems also to have its own period effect: witness the intellectual outpourings follow in eras of educational reform from Germany/Prussia after the 1780s and France during the 1880s and after.

One particular design feature that supports innovation seems to have been the importance of role hybrids; those with one foot in practical concerns and the other in a setting allowing for systematization of ideas are often especially innovative situations. A particular sociological example was the early development of survey research in which academic sociologists played midwives to the more sophisticated methodological development of the research technique.

The institutions within which social science development takes place may also have an effect on the dominant cognitive style through which social knowledge is produced and debated.

German scholars often were ensconced in universities, whereas French scholars debated within scholars. As a result:

> Whereas the German intellectual was systematic, scholarly, even pedantic, the French intellectual tended to be orientated to science as well as to political controversy and to be brilliant and lucid as well as facile and flowery in exposition. (Collins, 1994: p. 14)

Cognitive properties may affect the development of national traditions, where there is reliance on subject matter that is strongly localized; for example, the study of languages seems to have nurtured a considerable degree of longevity of localized scholarship. All cultures are permeated with a reflexive 'folk knowledge,' but one of the earliest arenas for the development of social science knowledge were the many prototypical 'folk languages' in which 'native scholars' extracted some of the formal principles of their language in order usually to in turn use these principles in instruction and structuring of the language itself by guiding its development.

Conclusions

Since the long nation-based period of development of sociology throughout the nineteenth century, the national traditions have tended to become overwhelmed by more recent international developments in sociology. Nevertheless, distinct traces of the older national traditions can be found, and the legacies of particular sociological traditions can often been linked back to these national traditions.

During the period of the most active development in our current social science disciplines, innovative work was largely carried out in national traditions, albeit within a context of considerable international exchanges of views. Some of the key intellectual/cognitive features of these national traditions can be traced back through some centuries of intergenerational conversations. It can also be shown that differential institutional arrangements involving the state, other organizations, and the institutional features of knowledge-producing structures have also shaped social science work in particular national jurisdictions. Although the high period of the play of national traditions has largely passed and social science now seems to be relatively universalistic, national contexts still continue to shape the work of social science in each national community.

Sociology tends to a complexity that sustains separate traditions. As well as maintaining an *extensive* scanning range of research interests tendencies to differentiation are aggravated still further by sociology's theoretical and highly developed self-consciousness and reflexivity. A broad problem is that there are somewhat inadequate mechanisms for bringing traditions together. Part of this arises because of the essential empiricism of US sociology (albeit laced with middle-range theories), which is globally hegemonic, now abetted by poststructural approaches but which fails to be too concerned with theoretical synthesis. Another general barrier to more active synthesis is the condition under which continental social theory is produced, which also too often stresses on the idiosyncratic features of theories and theorists, rather than cumulation. This reflexivity about traditions has allowed sociologists to maintain some degree of control over their own intellectual concerns. But, the issue still remains – do traditions shape sociologists' work, are they merely epiphenomena resulting from hard and clear choices that sociologists make, or is there some interaction between the two?

Sociology and Psychiatry

Abstract

Sociology and psychiatry have a longstanding, albeit intermittently, conflicting relationship. During the mental health care reforms from the 1950s to the 1980s, mainstream sociology has supported psychiatry with both basic and applied research. Currently, the sociological perspective has become more critical. From a sociological point of view, several so-called mental disorders are nothing but medicalized behavioral features (e.g., grief reactions as depression). Further issues addressed are the current countermovement against medicalization ('recovery') as well as the ongoing stigmatization and social exclusion of persons who are diagnosed with a mental disorder.

Introduction

Sociology and psychiatry have a long-standing relationship. More than 100 years ago Emile Durkheim (1897), commonly regarded as one of the founding fathers of modern sociology, has in fact taken suicide as a starting point for developing sociological theory. Within psychiatry, this research is also regarded as the beginning of research on the social context of mental disorders. During the twentieth century and especially in the second half the relation became intensified.

On the one hand, psychiatry has profited from cooperating with sociologists by making use of sociological research methods. Until the last quarter of the twentieth century, sociology was at times even a leading scientific discipline for psychiatry, and at other times, still one of the major background theories. Robert Straus' distinction into 'sociology in medicine' and 'sociology of medicine' (Straus, 1957) could be applied to psychiatry and is named here as 'sociology in psychiatry.' Sociological research has had a deep impact on transforming mental health care systems after World War II all over the Western world. Among other things, the term 'total institution' was taken to develop the deinstitutionalization process during the mental health care reforms.

On the other hand, this collaborative relation has changed recently into a separation. Currently, there are only very few sociological authors who contribute substantially to psychiatry and mental health care. Reasons for this separation can be found on both sides of the separation. One reason seems to be that after many decades of sociopsychiatric research, the mainstream of psychiatry turned to neurobiologically informed disease models during the 1980s and the 1990s. Within psychiatry, the 1990s is known as the 'Decade of the Brain.' Another reason was the apparent lack of practical suggestions from sociology after most of the mental health care reforms were put into place. Many psychiatrists had the impression that the sociological literature on their profession would result in nothing more than criticism on psychiatry in general.

Nevertheless, in many areas of psychiatric research empirical methods of assessment that have their routes in social science research are being used. The authors do not discuss these issues here, since quite a few other articles in the second edition of this encyclopedia deal with such aspects. The authors do not deal therefore with topics such as the epidemiology, i.e., the social distribution of mental disorders, and, potential social antecedents (e.g., social class, gender, social stress), and also not with illness behavior, services research, and the like. Also, they do not discuss what is called social psychiatry, community psychiatry, public mental health, and similar population-related practice aspects of promoting mental health, preventing mental disorders, and treating persons suffering from mental disorders. In addition to the other articles in this edition of the IESBS, several recent handbooks (e.g., Morgan and Bhugra, 2010; Pilgrim and Rogers, 2010; Aneshensel et al., 2013; Richter, 2003) as well as scientific journals (*Social Psychiatry and Psychiatric Epidemiology*; *Epidemiology and Psychiatric Sciences*; *International Journal of Social Psychiatry*, *Society and Mental Health*) cover these and similar topics. However, many of these publications also deal with topics that can be subsumed under the authors' main focus, the 'sociology of psychiatry,' so they are also a source of information for the present article. Finally, since the boundaries between sociology and other social sciences, such as anthropology, history, and economics, are blurred, the authors refer occasionally to these neighboring social sciences.

Before illustrating – in the sections below – sociological thinking on psychiatry and its practice with several examples (power and labeling, medicalization, empowerment versus the sick role, social exclusion and stigma) a few further comments are necessary to better understand sociologists' views on psychiatry.

From a sociological perspective, psychiatry's everyday practice and its epistemology are closely linked. This notion of a strong nexus of practice and epistemology stems from the 1950s and the 1960s. In these decades, psychiatry received strong sociological criticism on both its morally and politically exclusive practices as well as on the more or less hidden ideology of addressing deviant behavior. Deviancy and its moral connotations became the major focus of sociological and sociohistorical research on psychiatry. While stigma research has received much attention in collaborative research between psychiatry and sociology, it has been criticized that psychiatry regards itself as part of the solution but not as part of the problem when complaining about the stigma of mental illness (Sayce, 1998).

 http://dx.doi.org/10.1016/B978-0-08-097086-8.27068-2

Sociologists have dealt not only with psychiatric concepts but also with the process of professionalization of psychiatry, which is closely linked both to conceptual issues and to the practice of psychiatry. The rise of the psychiatric profession during the nineteenth century has been regarded alternatively as having been due to their functional value for economic order and efficiency under capitalism (Scull, 1979) and to its role for maintaining the moral, rather than the economic order (Foucault, 1961). Today, the recruitment of doctors into the specialty of psychiatry is declining, often to such a degree that it is discussed whether psychiatrists are an endangered species (Katschnig, 2010), while related profession such as psychologists and psychotherapists are on the rise.

While sociology has thus been ambivalent toward psychiatry – oscillating between cooperation and criticism – a similar ambivalence can be stated for psychiatry's perspective on sociology. On the one hand, the application of sociological research methods to psychiatric problems have undoubtedly contributed to raise psychiatry's societal visibility and importance, by furthering epidemiological and social psychiatric research, which has shown that between one-quarter and up to nearly half of Western populations suffer from at least one diagnosable mental disorder during a person's life time. On the other hand, sociologists are disliked by psychiatrists since they have been and still are among the most radical critics of psychiatry, concerning both its concepts and its practice.

Post–World War II Sociological Theory on Psychiatry: Power and Labeling

While being the work of a philosopher, the French Michel Foucault's analysis on the constitution of mental health care in the seventeenth century and its moral connotations (Foucault, 1961) was very well received within sociology. From his perspective, psychiatry was one of the major societal agencies during the modernization process that led to an increasing disciplining of people who showed 'strange' or unwelcome behavior. At this time, the 'strange' behavior was not yet seen as a medical condition. The purpose of the disciplining strategies was mainly to ensure that people who were regarded as being able to work did their work in the end. In the context of enlightenment, this perspective changed into a medicalized notion of unwelcome behavior. Benevolent physicians were convinced of the treatability of these conditions while the patients were held as inmates in so-called asylums. Thus, the medical subdiscipline of psychiatry evolved as part of the modernization of power, which led to the emergence of the modern state.

This historical view was taken up in sociology after World War II, when psychiatry became the target of humanitarian and politically driven critique, which eventually triggered the psychiatric reforms of the 1960s and the 1970s. Although twentieth-century's psychiatric care was completely different from that of the eighteenth century, major principles appeared to have remained. Sociologists became critics of the impersonal way in which patients were processed. Goffman (1961), in his famous study *Asylums* (the most sold sociological book worldwide), based on participant observation, coined the concept of 'total institution' for the mental hospital and similar organizations that disregard the personal needs of their inmates. According to Goffman, the common feature of 'total institutions' such as mental hospitals, prisons, and even concentration camps was the nonseparation of the social spheres work, life, and leisure under a single authority with very strict rules for the inmates.

Goffman did not only cover the institutional part of the asylum but also followed the then major sociological perspective on mental disease (or 'insanity' at that time). Insanity was not seen as a trait of the inmate but as an ascribed feature that was forced upon a person and that had significant consequences such as admission to a mental hospital. In line with the then prominent theory of symbolic interactionism, the response by the social environment to a certain behavior constituted what was later called a 'label.' Labeling theory (e.g., Scheff, 1966) became a prominent theory, as it was able to demonstrate the power of forced-upon labels. Labeling occurs after an observed and as such classified rule violation. The advocates of 'labeling theory' claimed that the same deviant behavior may either go unnoticed or be labeled as mental illness, depending on the circumstances in which it occurs and is perceived by others. For instance, in a now famous study, Rosenhan (1973) observed that healthy test persons ('pseudopatients') who presented themselves to psychiatric hospitals and told the doctor that they were hearing voices (saying 'empty,' 'hallow,' and 'thud') were actually admitted and received a psychiatric diagnosis.

Once labeled, so the theory goes, the person's identity and social status is significantly altered. Part of the process is that the labeled person internalizes the new identity ascribed to him or her and becomes trapped in the new role of a mental patient. Even if one might assume something like an existing mental disorder, in the end, the label is seen as much more powerful than the 'basic disorder.' The power of the label has got to be acknowledged, however, contrary to the 'labeling' advocates; the forced-upon label will not be accepted freely by the persons in question. Rosenhan's test persons did not accept the label of being mentally ill and they did not become psychiatric patients eventually. Thus, being labeled does not exclusively lead to become (so-called) mentally ill.

Until today, psychiatry is regarded by sociologists as being a part of the power mechanisms that are enforced by the state on its citizens. Compulsory admission and compulsory treatment are intrinsic parts of psychiatric services. Since the beginning of the twentieth century, the legal professions have been increasingly involved in the process of admissions to mental institutions in order to counteract what has been regarded as mismanagement by the medical professions. This has prompted sociologists to analyze the social processes involved. There are basically two sociological positions: those seeing the legal and the medical systems as two competing institutions (Mechanic, 1978) and those who argue that, in practice, they join to become one actor, a 'treatment-control' system that 'takes care' of residual cases viewed as problematic for society, although the written law distinguishes between treatment and control (Dallaire et al., 2000). In the United Kingdom and other countries, a different dimension has been added to this issue with the concept of a 'community treatment order,' which would allow compulsory medication for patients living in the community and would let the pendulum swing back to medical control (Pilgrim and Rogers, 2010).

Recent Sociology: Mental Disorder as a Medicalized Social Construct

In line with recent theoretical developments in humanities (e.g., linguistic turn in philosophy) and with postmodern theories (Richter, 1994), the notion that a mental disorder exists as an objective entity is being contested within sociology until present. The roots of the early sociopsychiatric theories are still present today; however, theoretical reasoning has become far more sophisticated.

Current intrapsychiatry discussions on the introduction of the fifth edition of the Diagnostic and Statistical Manual of Mental Disorders (DSM-V) by the American Psychiatric Association have once again triggered research into how mental disorders are being constituted by the psychiatric community. The ever-changing terminologies, concepts, and boundaries of single disease entities (e.g., depression, autism) have made it clear that a biomedical model of mental disorders with clear etiologies and a broadly accepted nosology will neither currently nor in the near future be at hand. Methodologically speaking, recent diagnostic manuals have favored interrater reliability over validity. This is in line with the above-cited studies and theories that questioned that there is a common understanding of what a mental disorder is even within the psychiatric community (Horwitz and Wakefield, 2007).

The obvious arbitrariness of diagnostic entities that are used for categorizing diseases has highlighted once again the questions of where normality ends and where a disease begins. The so-called categorical disease entities suggest more or less clear boundaries that are often hard to see. Many theorists since long have been favoring dimensional models over categorical ones. From a practical medical point of view, however, a categorical nosology has significant advantages (see the debate in Shorter and van Praag, 2010). Medicine as a professional practice and as a research community as a whole deals with disease entities. The categorical disease model has certainly helped to advance psychiatry as an acknowledged medical subdiscipline and thus has boosted its image and its credibility in terms of mental health practice and research. A closer look on specific diseases reveals, however, that apparently well-known diseases or disorders such as depression or schizophrenia do not exist as proper entities.

This state of conceptual and theoretical confusion in terms of psychiatric diagnoses supports the critical stance taken by sociologists. The most prominent sociological theory in this regard is called the 'medicalization' theory. Peter Conrad, its original author, has defined medicalization as a "… process by which nonmedical problems become defined and treated as medical problems, usually in terms of illnesses and disorders" (Conrad, 1992: 209). By being medicalized, a certain behavior and condition is subject to the execution of medicolegal power. A prominent example was homosexuality, which was listed as a psychiatric condition until 1973, but was initially defined in the 1950s as a 'sociopathic personality disturbance.' Until the end of the 1960s there was a strong psychoanalytically inspired tendency to diagnose and treat homosexuals in order to cure them from what was regarded as a "'phobic' avoidance of the other sex caused by inadequate parenting" (Drescher, 2010: 429). The removal of this 'disorder' from DSM-IV was an important step to normalization and destigmatization of same sex relations. In this regard, it can be seen as a sort of demedicalization (Conrad and Slodden, 2013).

More recently defined disorders that are assumed to be medicalized social behavior include the attention-deficit/hyperactivity disorder, the social anxiety disorder, and grief and bereavement disorders. The last of these had triggered a long debate within the mental health treatment community before DSM-V was launched. The debate centered on the question of whether the emotional state of somebody who lost a loved one is a psychiatric condition that needs to be treated. Grief is a normal and expectable reaction to loss. However, its symptoms may not substantially differ from depressive reactions after losing a job or facing a divorce. Thus, current psychiatry is challenged by a certain dilemma, namely, to follow its philosophy of disregarding the etiology of disorders or to be charged with the accusation of more and more medicalizing 'ordinary' problems.

Related to this dilemma is a recent debate that concerns the boundary between 'normal' behavior and conditions and sickness. Allan Horwitz and Jerome Wakefield, two distinguished social scientists, have triggered this debate with several publications. One major book deals with the question of how sorrows that have been regarded as normal in earlier decades (e.g., reactions to losses, grief) are seen as depressive disorders nowadays (Horwitz and Wakefield, 2007). A similar change has occurred with the development of 'normal' fears into anxiety disorders (Horwitz and Wakefield, 2012). From a sociological perspective, these changes can be seen as examples of medicalization.

In contrast to several other genuine sociological approaches, Horwitz and Wakefield have made a case for the incorporation of biological factors into modern sociological thinking on mental health. Their 'harmful dysfunction' approach aims at distinguishing disorders from nondisorders. Evolutionary designed psychological functions that cannot be performed are the basis of a new concept of mental disorders, according to their work.

Countermovements against Medicalization: Empowerment and Recovery versus the Sick Role

Today, those receiving care from professionals start to threaten traditional professional identities and psychiatry in general. They are themselves becoming more powerful in forming self-help and advocacy groups and tend to use terms, such as 'users,' 'clients,' 'consumers,' and even 'survivors of psychiatry,' instead of the term 'patients.' These terms have different implications of how the traditional doctor–patient relationship is redefined. 'Client,' as opposed to 'patient,' implies partnership instead of submissivity and passivity. The term 'consumer' goes even further in claiming that the patient has certain entitlements whose fulfillment can be sued. The concept of 'survivor of psychiatry' denies the right of psychiatry to intervene into the person's problems – it is related to the antipsychiatry movement, which has been set up by former patients and therapists who reject the notion of mental disorders to exist. Pilgrim and Rogers (2010) give a detailed account of sociological thinking about these issues and how the situation has changed since Talcott Parsons (1951) has formulated the paradigm of the 'sick role.' According to Parsons, the sick role allows people to be temporarily exempted from social responsibilities, but, in exchange, they must accept that they cannot get well on their own, and that they have to look for professional help.

Another important development, which can, at least to some extent, counteract the medicalization of mental disorders is the Recovery and Empowerment movement (Amering and Schmolke, 2009; Slade, 2009). This interesting development might be able to reconcile, at least to some extent, mainstream mental health treatment with its critics. Under the labels of 'Empowerment' and 'Recovery' the experiences of persons with long-term mental health problems are included into the planning, delivery, and quality control of mental health services. Both concepts aim at enhancing the self-management of people who suffer from mental health problems. Recovery, additionally, supports users in developing an identity that goes far beyond the patient role. Finally, it aims at leading a meaningful life despite having had or still having mental health problems or disabilities. An important component of Recovery is providing support by peer users who are increasingly employed by psychiatric services.

Interestingly, the role of sociologists in supporting or evaluating this important shift is rather marginal. Only few sociological contributions on this topic have been published so far (Watson, 2012). This is astonishing because central sociological topics are addressed in these concepts. The empowerment of persons with mental health problems, and thus, the weakening to a certain extent of the role of 'traditional' professional, is one of the long-standing goals of sociological work in this field. A related issue to Recovery aims at addressing the social exclusion (see below) and enhancing the social inclusion of persons with mental health problems into society. However, only few sociologists nowadays conduct research into the entire field of mental health and into social exclusion problems of persons with mental health problems in particular.

The countermovement against medicalization and therapeutically induced despair could be a very interesting phenomenon from a sociological perspective. As sociologists have shown (Yanos et al., 2007), the marginalized group of socially excluded persons with mental health problems has fought a social fight against strong powers within the therapeutic and scientific communities. More and more, professions from the mental health treatment field, e.g., psychiatric nurses, regard the Recovery movement as a very helpful aid in achieving better treatment results. This, however, becomes a contested issue within the user movement as it is suspected that psychiatry uses patients to convince skeptical persons over to be treated.

Social Exclusion and Stigma

Persons with mental health problems are socially excluded from nearly every domain of the social world (Wright and Stickley, 2013). In economic terms, they are – on average – poorer than the healthy population and they suffer from a higher rate of unemployment. During the current economic recession, the unemployment risk for persons with mental health problems has risen further (Evans-Lacko et al., 2013): they are less often engaged in intimate partnerships, they are often deprived of legal and political rights, they are less often politically engaged, and they suffer from more physical health problems than their mentally healthy fellow citizens (Eikelmann et al., 2005). Another issue is the high rate of being victimized by aggressive acts.

This modern kind of social exclusion has taken over the longtime social exclusion of the 'insane' in asylums. By initiating the mental health reforms of the postwar decades, social and community psychiatry aimed at preventing any kind of social exclusion from which the persons concerned definitely suffer. Following the deinstitutionalization of mental health care, the former 'inmates' were supposed to live in the community (mainly in sheltered housing facilities) and to work in sheltered workplaces. It was assumed that many of those persons could be trained to lead an ordinary life and to be released from professional support.

However, from the current perspective, it becomes clear that the mental health care reforms did not succeed in terms of social inclusion. From a sociological point of view, it is clear that the initial ideas of social inclusion did not fit the conditions of modern societies. As the postwar societies in the Western world became more individualized and differentiated and as the social change happened more quickly than expected, many persons with mental health problems could not keep up with the challenges of modern life. Unfortunately, the postwar treatment system with its supporting and sheltering institutions had contributed unintentionally to the social exclusion by creating living conditions that were often not compatible with the conditions of the 'real' world.

It is currently debated whether – in the light of societal and political conditions that apparently are not supportive – individual support for reinclusion is an effective strategy (Clifton et al., 2013). To give an example, from a research perspective, supported employment is an effective strategy that aims at supplying persons concerned with a real-world job and with a job coach who is able to provide backup and encouragement when facing strains and problems. This strategy, however, cannot be successful when the general unemployment rate is high and persons with mental health problems are being discriminated against.

In addition to social exclusion, the social stigma of mental disorders, mentally ill persons, and mental health treatment facilities is persisting. Stigma research with regard to disability and illness is one of the most commendable contributions of sociology to health care in general and to psychiatry in particular (Goffman, 1963; Link and Phelan, 2013). Stigma research and the resulting antistigma initiatives have gained a lot of attention over the recent decades. As can be easily concluded, the stigma on mental disorders and on the persons concerned has a close connection to the social construction of mental health and illness. Bruce Link and Jo Phelan have, therefore, suggested to analyze stigmata by using a 'modified labeling' approach. The authors suggest that "… stigma exists when elements of labeling, stereotyping, separation, status loss, and discrimination occur in a power situation that allows them to unfold" (Link and Phelan, 2001: 367).

Being stigmatized can lead to severe consequences for the affected persons. Persons with mental health problems report about status loss and experiences of being discriminated against openly (Link and Phelan, 2013). Additionally, the social network tends to decrease in many cases after the diagnosis has become known to friends and acquaintances. From a therapeutic point of view, stigma management becomes an important issue. Recovery care includes dealing with questions such as to whom to disclose the 'illness,' when to talk about

mental health problems while setting up new relations, and also to discuss legal questions as if employers have to be informed about being treated for a mental disorder.

Bernice Pescosolido has recently summarized the relevant research activities as well as the knowledge from the US perspective (Pescosolido, 2013). Similar to experiences in Germany (Angermeyer et al., 2013), the attitudes of the general public have not changed much during the recent decades. However, the American public has become more sophisticated and probably more open when it comes to recognizing and disclosing mental health problems. This social change in relation to mental disorders is regarded as one factor that has led to steadily rising rates of mental health treatment utilization (Richter and Berger, 2013; Richter et al., 2008).

Conclusions

The relationship between sociology and psychiatry can be characterized as oscillating between cooperation and criticism of each. After a long time of close collaboration between sociology and psychiatry in the second half of the twentieth century (which was accompanied by the antipsychiatry movement), the current situation can be outlined not only as one of increasing interest in one another but also as being suspicious about each other's contributions. Given alone the persisting problem of the arbitrariness of the classification of mental disorders, sociological criticism of psychiatry does not seem to disappear. However, today's mental health care practice is increasingly including social aspects and moving toward psychosocial interventions once again, after the 'decade of the brain' has not succeeded in providing effective and efficient treatments for most mental health disorders. Psychiatrists might consider inviting sociologists to carry out more studies on these modern practices. It remains to be seen whether these new developments will help to bring sociology and psychiatry closer again.

Sociology and the New Institutionalism

Abstract

In sociology, new institutionalists led the revival in interest in institutions in organizational theory and economic sociology by shifting the focus of causal reasoning from agent-centric studies of economic and organizational actors to the relationship connecting the firm with its institutional environment. We suggest a multilevel causal model incorporating the connection between the subinstitutional domain of social action and concrete social relationships, and the meso- and macroinstitutional environment of customs, conventions, law, organizations, ideology, and the state as the key elements explaining the rise and demise of institutions. In this model, norms bridge the microworld of individual actors and social groups, and the broader institutional environment.

The new institutionalism and the focus on institutions for its foundational concept have gained ascendancy in economics, political science, and sociology. The claim that institutions matter is now a widely held assumption, which addresses a cross-disciplinary set of problems germane to organizational and economic performance. The interest in institutional analysis has given rise to a variety of new institutionalist approaches. Not since the behavioral revolution of the 1950s has there been a foundational concept that has generated so much interest, exchange, and debate in the social sciences. The variety of research programs inspired by the new institutionalism has produced robust findings that have cumulatively answered questions of basic interest to the social sciences. Although the new institutionalisms incorporate a broad variety of approaches with distinctive emphases, the common interest in institutional analysis involves a shared behavioral assumption of bounded rationality (Simon, 1957). The Coasian revival of economic interest in institutions through transaction cost reasoning provided a method that enables economics to 'study the world that exists,' which new institutional economists extended to a series of seminal work that explained a broad range of economic and organizational outcomes. In sociology, new institutionalists led the revival in interest in institutions in organizational theory and economic sociology by shifting the focus of causal reasoning from agent-centric studies of economic and organizational actors to the relationship connecting the firm with its institutional environment.

A broad consensus across the social sciences agrees that norms are mainly effective in the governance of exchange in close-knit communities of economic actors. These settings typically involve tribal and peasant societies, or in advanced industrial societies, highly specialized markets with a limited number of market players engaged in repeated exchange. Detailed case studies highlight the variability of motivations and mechanisms of private ordering applied in close-knit networks. Diamond traders, for example, systematically reject state-crafted law as insufficient for the specific business risks inherent in the diamond industry. Traders instead rely on a sophisticated extralegal contractual regime including arbitration proceedings enforced by trading clubs designed to disseminate information about reputation among members (Bernstein, 1992). A study of conflict resolution among cattle farmers in northern California sheds light on less-standardized procedures. Despite their differences, a common identity as ranchers of Shasta County sustains a live-and-let-live philosophy, which enables parties to practice mutual restraint. As long as accounts balanced along multiple dimensions of interpersonal relations, parties in disputes settled informally. In sum, private orders rely on norms to secure contracts through repeat transactions and community sanctions in close-knit communities and networks (Ellickson, 1991).

In their study of the rise of capitalism in China, Nee and Opper (2012) examine the broad-based robust entrepreneurial action supported by endogenous economic institutions arising from interacting individuals. They show that mutual dependence – on information flows, on access to scarce resources, on interfirm collaboration in technology development, and on privately organized supply networks autonomous from government-controlled sources – can provide the glue that endogenously reinforces long-term stability of contractual relationships, without reliance on third-party enforcement. Social norms can enable close-knit communities to successfully avoid the 'tragedy of the commons' problem in managing communal resources (Ostrom, 1990). Such governance structures rely on long-standing social relationships and community sanctions rather than on external authority to solve the collective action problem threatening the depletion of communal resources.

The Origin of Norms

Most norms evolve gradually through trial and error, with the behavior that brings about success reinforced. Benefits from norm-compliance, however, are not limited to tangible gains such as commodities. If the total gains from cooperation exceed the costs, private orders can provide a stable framework for economic actors to sustain repeat transactions. This is consistent with the causal sequence in the rise of political and economic institutions in the West. Norms often precede laws, and only become formalized, Robert Axelrod observes, once a "norm becomes firmer" and once "there is growing support to formalize

it through the promulgation of laws" (Axelrod, 1984). Civil liberties, he continues, the very foundation of democratic systems, exemplify this: "The legal system can only protect free speech if there is substantial support for it among a population willing to tolerate dissent and willing to protect those who exercise it" (p. 1106). Conformity between legal rules and social norms is therefore often the result of this particular sequence where laws simply support, maintain, and extend what is regarded as a just and appropriate social norm. As with political institutions, economic law often builds on established and widely accepted business norms. In Amsterdam, home of the world's first stock market and stock company (the East India Company, founded in 1602), formal shareholder rights were largely absent, and many of the financial transactions were even prohibited by law. Securities trading relied on self-interest and self-enforcement. It was not until 1851 that the Amsterdam Stock Exchange Association was founded to organize and regulate share trading. Also the London Stock Exchange did not receive its first codified rule book until 1812, while organized securities trading had started as early as 1698. The Brussels stock exchange worked for more than 100 years up to 1935 with minimal government regulation. Worldwide, the inception of securities markets was not usually preceded or even accompanied by formal state-mandated rules protecting shareholder rights. Company stocks were traded informally and transactions were treated as gentlemen's agreements, often conducted in local coffee houses or open marketplaces. Hence, new institutionalist economic sociology agrees with economic new institutionalists that good formal institutions have typically followed, rather than preceded, economic development (Glaeser et al., 2004).

In the new institutionalist economic sociology, institutions are self-reproducing social structures that provide a conduit for collective action by enabling, motivating, and guiding the interests of actors and enforcing principal agent relationships. Institutions comprise a system of interrelated informal and formal elements – customs, conventions, norms, beliefs, and rules – governing social relationships within which actors pursue and fix the limits of legitimate interests.

Norms and Formal Rules

Economic sociologists have long held the view of markets as self-reproducing social structures within which buyers and sellers transact across market interfaces. "However difficult it often is to account for all their detailed characteristics," market institutions "are at least the product of the very things economics disregards – the relatively permanent relationships between individuals or between groups, which form social structures" (Homans [1961]1974: p. 68). Economists concur that repeated exchange is commonplace even in markets characterized by the ease and reliability of impersonal exchange. In addressing how to characterize the market not as an abstraction but as a self-reproducing social structure, White proposed "embedding economists' neoclassical theory of the firm within a sociological view of the market" by integrating signaling theory into a sociological model of markets (White, 1981: p. 518; for signaling theory refer to Akerlof (1976) and Spence (1974)). In White's model, firms are like organisms seeking out niches in an ecology. Markets develop as endogenous institutional constructs as firms watch signals emitted by their competitors and position themselves to compete in a niche, "compatibly arrayed on the qualities which consumers see in them" (White, 1981: p. 519). The challenge to demystify markets calls for examining the relationship between norms embedded in informal social processes and the formal rules mandated and enforced by the state.

A multilevel causal model (see **Figure 1**) portrays the connection between the subinstitutional domain of social action and concrete social relationships, and the meso- and macroinstitutional environment of customs, conventions, law, organizations, ideology, and the state. In this model, norms bridge the microworld of individual actors and social groups, and the broader institutional environment (Nee, 1998). We assume that actors are rational in that they make decisions according to cost–benefit criteria. However, we do not see humans as the narrowly self-interested *homo oeconomicus* of neoclassical economics, possessing perfect information and unbounded cognitive capacity. Instead they use rule of thumb heuristics based on the information currently available to them (Marsh, 2002). The arrows pointing downward from the institutional environment indicate constraints placed on social action. The arrows pointing upward indicate that the macro environment is constituted and modified by social action. Economic actors can through collective action trigger changes in the institutional environment. Not only do informal norms gain in importance if many actors find it rational to decouple from existing formal rules, but once a critical mass is reached, the collective action of economic actors imposes pressure on

Figure 1 A multilevel causal model of institutions. Source: Nee, Victor, Opper, Sonja, 2012. Capitalism from below: Markets and Institutional Change in China. Harvard University Press, Cambridge, MA.

the state to respond by enforcing the existing legal and regulatory structures. Once this tipping point is reached, the state no longer can effectively enforce compliance in the face of a self-reinforcing collective action. This process of collective action can but need not involve formal types of lobbying.

The institutional mechanisms are distal, as opposed to the proximate mechanisms at the micro- and mesolevels of individuals and networks. Institutional mechanisms encompass the deeper causes because they shape the incentive structure for organizations and individuals, and thereby the contexts in which proximate mechanisms operate. The institutional-level mechanisms posited by economists and sociologists, despite differences in behavioral assumptions and conceptual language, are not as far apart as is commonly perceived (Nee, 2005). Market mechanisms schematically represented in the downward arrow from the institutional environment to organizational fields includes those embedded in labor markets, capital markets, raw material markets, and so on. The formal rules that make up the institutional environment and norms embedded in ongoing social relations, then jointly interact to shape economic behavior in the market place.

Actors are motivated by interests and preferences, often formed and sustained within close-knit groups. Groups of firms in turn are commonly arrayed in a variety of organizational fields, defined as a matrix of organizations that, "in the aggregate, constitute a recognized area of institutional life; key suppliers, resource and product consumers, regulatory agencies, and related organizations that produce similar services or products" (DiMaggio and Powell, 1983: p. 148). The production market is thus embedded in its organizational field as the core firms in a distinct niche. In the production market, firms compete and maneuver for advantage and status with peer firms in the same niche (White, 1981). Given uncertainties of upstream and downstream market conditions, they are guided by the signals they read from the operations of their peers. In competitive markets, pressures on firms stemming from Darwinian selection processes necessitate an interest-related logic of strategic action.

Within organizational fields, processes of conformity – *isomorphism* – motivate and guide organizations, endogenously giving rise to increasing within-field homogeneity. Paul DiMaggio and Walter Powell specify three mechanisms – coercive, normative, and mimetic – promoting isomorphism in organizational fields (DiMaggio and Powell, 1983). Coercive isomorphism integrates resource dependence theory into organizational analysis and assumes that organizations respond to societal claims and preferences; normative isomorphism specifies how professional associations influence organizational behavior under conditions of uncertainty, and mimetic isomorphism is about how facing uncertainty under high stakes, intendedly rational actors satisfice by looking for successful competitors and making plausible but incorrect guesses about the reasons for their success. Organizations tend to mimic other similar organizations that they perceive to be successful. Legitimacy-seeking is driven mainly by the firm's interest in its survival and profitability. Legitimacy can be viewed as a condition of fitness, which enables firms to enhance their survival chances and secure advantages in economic and political markets. For manufacturers especially, mimicking entails learning-by-doing in efforts to internalize the technological and organizational basis of success of leading competitors. As Kenneth Arrow showed, self-perfection and minor innovations gained by learning from experience in ordinary production drives endogenous economic growth (Arrow, 1962).

The social mechanism guiding the action of firms in an organizational field is not dissimilar from those influencing strategic action of individuals in close-knit groups. The process through which conformity is achieved has coercive, normative, and mimetic aspects (Homans [1961]1974; Emerson, 1962; Blau, 1964). Organizational actors are motivated by interests and preferences, often formed and sustained within the organizational field. Rationality is context-bound and embedded in interpersonal ties. Only if individual interests and preferences are well aligned with the incentives structured in the institutional environment, will they reinforce compliance with formal rules through self-monitoring and enforcement. Otherwise, if individual interests are not aligned with the structure of opportunity legitimized by the state, strategic interest may give rise to decoupling from institutionalized norms (Merton, 1968), which may in turn lead to the formation of opposition norms once a sufficient number of actors arrayed in organizational fields decide to decouple from the formal framework (as discussed below).

In this multilevel causal model, institutional change rests on four causal mechanisms, linking the subinstitutional domain of social action with the macroinstitutional environment as follows: First the market mechanism provides incentives and opportunities for economic actors to come up with bottom-up institutional arrangements to enable the growth of the private enterprise economy. Second, through random *mutations* institutional innovations emerge and through a process of trial and error, successful forms diffuse through the regional economy. Third, through *mimicking* of successful business ventures, swarms of followers pile into the niche leading to spatial geographical concentration. Fourth, *mutual monitoring and enforcement* in crosscutting networks of economic actors reinforce social norms.

Norms and Networks

What explains motivation for trustworthiness and abstention from opportunism in ongoing social relationships? Why is trustworthiness found more commonly in ongoing social relationships than in transactions between strangers? The answer is found in specifying the mechanisms intrinsic to social relationships that develop and maintain cooperative behavior, enabling actors to engage in collective action to achieve group ends. These mechanisms are rewards and punishment in social exchange and their use in upholding norms – shared beliefs and expectations. Numerous studies confirm the efficacy of social rewards and punishment in motivating trustworthy behavior and abstention from opportunism with respect to the norms of the group (Whyte, 1943; Barnard, 1968; Abolafia, 1996; Bewley, 1999). Informal norms arise in the course of social interaction as standards of expected behavior and are maintained when reward is expected to follow conformity and punishment, deviance. Members of a group routinely reward conformity to norms by conferring

social approval and status. Conversely, members punish failure to conform to norms through their social disapproval and, ultimately, through ostracism. Hence, the monitoring of norms is a spontaneous by-product of social interactions. In more complex exchanges, the same processes hold, but the pressure to conform also takes on a collective action dimension. Frequency of interaction, a characteristic feature of close-knit groups, lowers the cost of monitoring members, assuming they are in close enough contact with one another that information about members' conduct is common knowledge (Hardin, 1982; Macy, 1991; Gould, 1993). Reward and punishment in repeated exchanges – when actors take into account the weight of the future, as in ongoing relationships – motivates cooperative behavior. Community sanctions complement bilateral responses, if transactions are infrequent. In sum, trustworthiness and reliability as forms of cooperative behavior arise from rational action responding to social rewards and punishment in ongoing relationships.

In his detailed account of the interactions in a work group made up of a supervisor, 16 agents, and 1 clerk, Peter Blau provides an illustration of how self-interested action of individuals endogenously produces a pecking order through the exchange. Agents consulted fellow agents about the appropriate legal rules that applied to their case, rather than bring their questions to the attention of the supervisor who evaluated their work. The importance of social rewards and sanctions (e.g., status) in the normative regulation of a social structure are highlighted here. Routine social exchanges, like repeated transactions and community sanctions, comprise glue for the bottom-up institutional arrangements that endogenously arises to sustain long-term economic relationships. The behavior of economic actors frequently bears little resemblance to the legitimate courses of action stipulated by state-mandated formal rules. Instead, social groups based on personal connections serve to organize market-oriented economic behavior according to norms reflecting the private expectations and interests of individuals. They act often at odds with the goals formulated by politicians.

Norms operating in the shadows of state-mandated rules can both limit and facilitate economic action. On the one hand, a decoupling of norms from these rules can give rise to inefficient allocation of resources when individual actors collude to secure resources from government for their group, resulting in structural rigidities and economic stagnation (Olson, 1982). In Russia, mafia-like business networks operated to obstruct Boris Yeltsin's efforts at building a market economy. On the other hand, a decoupling of norms can also facilitate economic action and promote growth by providing a framework for trust and collective action. In China, informal privatization and local institutional arrangements have contributed to two decades of economic growth during the early stages of economic reform.

The Quest to Understand Institutional Change

What accounts for the difference in results? Given the variance of possible interactions between formal rules and social norms, it is a central task for theory development to better specify the nature of the relationship. Under what conditions will norms evolve into self-reinforcing opposition norms, which then undermine the effectiveness of formal rule? By opposition norms we refer to beliefs that enable, motivate, and guide collective action decoupled from and not legitimated by state-mandated rules. Opposition norms are commonplace in all societies and span a wide range of activities, be they those of alienated minority youths in America and Europe or the untaxed economic transactions between buyers and sellers in the informal economy of established market economies. Especially in the early stage of norm emergence, opposition norms often involve 'subterranean' activity below the radar of the state, and thus are not detected by law enforcers. (For an analysis of opposition norms in response to external sanctions, see Heckathorn (1990).) They can remain below the radar indefinitely, but at an inflection point, opposition norms can burst into the public arena to enable, motivate, and guide self-reinforcing collective action compelling politicians to respond. Political elites face a range of options in their response, from strengthening law enforcement and use of coercive force to adaptive institutional change.

To understand the link between opposition norms and endogenous institutional change, it is crucial to explore the role of private order allowing members of social subgroups to improve their welfare position, although the state is unwilling or unable to protect their economic transactions. Clearly, to the extent that social groups have interests and preferences independent of what politicians or organizational leaders want, the respective contents of social norms and organizational rules will emerge to 'bend the bars of the iron cage' imposed by formal rules. Norms are ideas that arise from the problem-solving activities of human beings in their strivings to improve their chances for success (the attainment of rewards) through cooperation. Individuals jointly produce and uphold norms to capture the gains of cooperation (Nee and Ingram, 1998). (Ellickson (1991: p. 167) argues in a similar vein, "Members of a close-knit group develop and maintain norms whose content serves to maximize the aggregate welfare that members obtain in their workaday affairs with one another.") Such norms arise through trial and error and are adopted by members of a group when they result in success. Hence, norm emergence involves a collective learning process in which members learn from experience gained through different strategies and gradually identify the one which seems to have an edge over others. (Experimental research confirms that subjects prefer to learn to cooperate than not cooperate in repeated public good games. See Isaac et al. (1994).) In this sense, established norms are focal points, which evolve through social learning processes (Young, 1996).

Whether decoupled norms operate only under distinct circumstances or more widely, developing into self-reinforcing opposition norms leading to endogenous institutional change, depends on whether a critical mass of societal participation is reached (Young, 1996, 2001; Nee and Opper, 2012). For instance, in all command economies it was commonplace that individuals and firms sought to alleviate shortages of the formal economy by resorting to black market activities and barter trading (Kornai, 1990). While this practice was against the formal rules, it never gave rise to endogenous institutional change. Although company managers hoarded goods and repair parts to prepare for unexpected shortages, these activities

remained limited in scope. In retrospect, the scattered occurrence of black markets and barter trading may have stabilized the system, as companies were better able to respond to temporary shortages. Similarly, black markets may have helped to contain social discontent.

Conclusion

In sum, the new institutionalism is a cross-disciplinary paradigm involving sociology, economics, and political science contributing to the understanding of the workings of institutions. Economic sociologists emphasize the role of informal institutional elements of norms and networks in enabling, motivating, and guiding economic action. In the sociological approach, the emphasis is on bottom-up sources of creativity and innovation in the emergence of economic institutions facilitating economic activity and organizational performance. In an effort to broaden understanding of phenomena of institutional innovation and change, economic, and organizational scholars employ a multilevel causal model where causal forces operate in both directions from institutional mechanisms embedded in macro structures to microlevel behavior, and from micro motives and behavior to the macro level. In the new institutionalist approach, the task of cumulative empirical effort is to identify both commonalities but also distinctive conditions shaping and facilitating bottom-up processes of institutional change.

Abstract

Three aspects of the epistemology (or philosophy) of sociology are examined: its ontology, epistemology in the narrow sense, and methodology. The matter of the nature of the social has two foci: the idealism–materialism dilemma and the individualism–holism–systemism trilemma. The main schools in the knowledge of the social are skepticism, apriorism, empiricism, and realism. And the discussions on the methodology of social research include empiricism (priority of data collection), interpretivism (or hermeneutics), and scientism (which combines data collection with theorizing). Finally, the sociology–epistemology connection and the sociology of epistemology are examined. The virtues and flaws of the various stands are pointed out, and reasons for favoring systemism and realism are proposed.

The word 'epistemology' will be taken here in its etymological acceptation, which is the one kept in the Romance languages, namely as philosophy of science. Up until the mid-twentieth century, physics and mathematics held the attention of most philosophers of science. The earliest anthology in the philosophy of social science appeared in 1968, and the *Philosophy of the Social Sciences* quarterly was born two years later. Since then, the discipline has been thriving. We will restrict our attention to the philosophy (or epistemology) of sociology. Three aspects of this discipline will be examined: its ontology, epistemology in its narrow sense (as the theory of knowledge), and methodology.

The matter of the nature of the social has two foci: the idealism–materialism dilemma and the individualism–holism–systemism trilemma. The main schools in the epistemology of the social are skepticism, apriorism, empiricism, and realism. And the discussions of the methodology of social research include empiricism (priority of data collection), interpretivism (or hermeneutics), and scientism (which combines data collection with theorizing). Finally, the sociology–epistemology connection and the sociology of epistemology will be examined. The virtues and flaws of the various stands are pointed out, and reasons for favoring systemism and realism are proposed.

Like any other special branch of the philosophy of science, the philosophy of sociology may be construed as having three main components: ontology (or metaphysics), epistemology in the narrow sense, and methodology (or normative epistemology). This order is not arbitrary, for every research strategy depends upon the type of knowledge being sought, which in turn depends on the nature of the thing studied. Thus, if the object of study is concrete, like a photon or a social group, and if what is sought is some objective knowledge of it, then the scientific method will be adopted. If, by contrast, the object of knowledge is assumed to be spiritual, and if things spiritual are deemed to be beyond the reach of science, then an alternative method will be preferred – such as revelation, intuition, interpretation (Verstehen), unchecked speculation, or narrative. In this article the ontology, epistemology, and methodology of sociology will be examined.

Ontology: Nature of the Social

The Idealism–Materialism Dilemma

Most sociologists adopt the vulgar view that the human being is a composite of body and mind (or spirit or soul), and do not ask how these two components are kept together. Hence, they do not characterize social facts as either material or spiritual, and do not worry about the place of sociology in the system of human knowledge: they are dualists. But some sociologists do worry about these questions, and argue for or against one of two monistic worldviews: idealism or materialism. Idealism is the view that everything is either ideal or ultimately ruled by ideas or symbols, whereas materialism holds that all existents are material or concrete.

In social studies, the idealism–materialism cleavage appears notably in the place and relative weight assigned to the so-called ideal (cultural and political) superstructure vis à vis the material (biological and economic) infrastructure. This very distinction betrays a dualistic stand, even if the preeminence or priority of either 'structure' (system) is postulated.

Consistent idealists will assert that everything social is spiritual (or cultural), whence sociology is a *Geisteswissenschaft* (science of the spiritual). This is the view of hermeneutics, symbolic interactionism, phenomenological sociology, and ethnomethodology. By contrast, materialists assert that persons and social groups are material, though not necessarily confined to the physical or even the biological level. And, unlike idealists, they claim that all cultural and political activities are influenced or even determined by environment, reproduction, and material production. Although it is undeniable that the reproductive patterns and means of subsistence condition culture and politics, it is no less true that the latter in turn help shape the former. In a systemic perspective, changes in the environment and in any of the subsystems of society (the biological, economic, political, and cultural) may initiate processes altering any of the others. People may work or fight, live or die, for King and country, no less than for food and family. There is no 'last analysis.'

Marxism is the oldest, and still the most influential, of the materialist schools in social science. However, given its proposed division between the material infrastructure and the ideal superstructure, it is questionable that Marxism is

 http://dx.doi.org/10.1016/B978-0-08-097086-8.32146-8

consistent. Moreover, philosophical Marxism is nowadays split into a large number of different schools, none of which is flourishing. By contrast, some of Marx's contributions to social science have survived, particularly his emphases on production, on the economic roots of the power elites, and on the economic causes of many an international conflict. Even some of Weber's studies are materialist, particularly those of the congruence between Hinduism and the Indian caste system, and on the causes of the decline of slavery in ancient Rome. Likewise the *Annales* historical school owes much to Marx.

Evolutionary psychology, the inheritor of sociobiology, is the newest and most popular materialist school in social studies. The evolutionary psychologists hold that everything social is ultimately biological, having evolved as an adaptation to the natural environment. This view overlooks all the types of self-destructive and antisocial behavior, from suicide to military aggression to environmental degradation to gullibility and ideological zealotry. And it ignores all social inventions (like formal education) and social revolutions (like the information revolution) – hence it is basically conservative. The evolutionary speculations on the origin of mental faculties are even more far-fetched and they lack empirical support. Still, something does remain of the attempt to reduce social science to biology, namely, the reminder that sociologists cannot afford to ignore human physiology and ecology. For example, they should not ignore that malnutrition stunts development and limits productivity; that plagues, foreign invasions, and wars are bound to eliminate some genes and change the immune system; and that a few more centuries of uncontrolled environmental degradation is likely to make our planet uninhabitable.

Evolutionary psychology, which is purely speculative as well as radically reductionist, should not be confused with either social cognitive neuroscience or neurosociology, which are brain-centered and abound in important empirical findings. One of the most striking recent findings is that the human brain contains plenty of 'mirror neurons' which are activated by the perception of other people's actions. The discoverer, Giacomo Rizzolatti, has suggested that our possession of such neurons in abundance explains social emotions, in particular empathy, and thus our spontaneous tendency to associate with others to constitute more or less permanent social systems.

The Individualism–Holism–Systemism Trilemma

There are essentially three consistent views on social structure: that it does not exist, that it is self-existing, and that it is a property of a system composed of individuals. The first, or individualism, identifies 'society' with 'crowd.' The second view, or holism, regards society as an organism, and the individual as wholly subordinated to it. The third, or systemism, views society as a system made up of individuals linked to one another by ties of different kinds and strengths. Individualism stresses agency at the expense of structure, and tends to explain action in terms of 'rational' (self-interested) decisions. Holism emphasizes collective traits, which it claims to be unexplainable, and it explains individuals by wholes. Lastly, systemism admits the novelty of systemic properties, as well as the possibility of explaining them in terms of interactions among individuals and systems.

Individualists rightly see in individual action the root of everything social. And even if they acknowledge the importance of the social context or situation, they resist the very idea of a social system (family, village, firm, etc.) Radical individualism cannot work in sociology if only because the idea of an individualist social science makes as much sense as Lebon's idea of crowd psychology. After all, sociology studies social facts, and although these result from individual actions, they have nonindividual traits. Families, businesses, schools, armies, religious congregations, and other social systems are structured groups, and a structure is a set of relations, among them the bonds holding the system together. Likewise, social processes, such as trade, governance, and war, are impersonal affairs. This is why there are no radical individualist sociologists, with the possible exception of Homans. Many who call themselves methodological individualists, from Weber and Pareto to Coleman and Boudon, admit the peculiarity of the social, and only attempt to explain it as emerging from individual actions; they may be said to be closet systemists.

Holists, from Aristotle to Hegel to Parsons to Luhmann, rightly emphasize the global (or emergent) properties, as well as the centrality of connections. But they exaggerate in claiming that social structure precedes and dominates individuals. This view, radical structuralism, is logically untenable, because there are neither wholes without parts, nor relations without relata, nor networks without nodes. In reality there are only interrelated individuals: relations, like their relata, are only the products of abstraction. For instance, there is no such thing as 'married' in itself, any more than there are unrelated spouses. Hence relations cannot act upon individuals, but interrelated individuals can alter or even sever some relationships – though never all of them at the same time except through suicide.

Systemism, first proposed by Holbach, and often confused with holism, is a sort of synthesis of the latter with individualism. It holds that, because individuals are interrelated, individual behavior can only be understood in terms of intentions as well as social constraints and stimuli. Thus, agency and structure are mutually inseparable. And social change, though brought about by individual action, consists in structural change – that is, change in the nature and strength of the bonds that hold social systems together. A social system may be characterized by its composition, environment (natural and social), structure, and mechanism. A change in any of these features may modify the other three. However, some features may resist changes in the others. For example, social order may survive demographic turnover and environmental catastrophe. Still, all four aspects coexist and, in the long run, important changes in any of the components are bound to alter the other three. Yet individualism ignores structure and underrates environment, whereas holism ignores composition and mechanism, and underrates the natural environment. Only systemism accounts for all four, and is thus likely to favor realistic models of social groups and effective social policies.

Epistemology: Knowledge of the Social

There are as many views on the nature of social studies as general views on the nature of knowledge: skepticism, apriorism, empiricism, and realism.

Skepticism

Skepticism comes in two strengths: moderate (or methodological) and radical (or systematic). The moderate skeptic doubts a thesis as long as no solid evidence for it is available. By contrast, the radical skeptic questions the very possibility of knowledge of some kind. Whereas moderate skepticism is part of the scientific attitude, radical skepticism is destructive and even self-destructive, because if everything is doubtful, why not skepticism itself? The variety of radical skepticism most common concerning the social is cognitive relativism, or the view that social facts cannot be known objectively. This view has been falsified by the growing pile of reliable social data and approximately true sociological hypotheses. Because every research project sets out to find out the truth about something, it presupposes the ability to find it.

Apriorism

Apriorism is speculation without reality checks. The 'grand social theories' of old were aprioristic. So are the evolutionary conjectures on the alleged genetic roots of all social traits, from the incest taboo to social stratification to ideals of human beauty. However, nowadays the most popular a priori theories in social studies are the rational choice models. All of these assume that we always act in self-interest and, moreover, that we proceed 'rationally,' that is, seeking to maximize our expected utilities. These theories are a priori because they are seldom if ever checked against empirical data. In particular, they postulate that agents have certain preference rankings (or utility functions), which are seldom checked. Moreover, some rational choice models are untestable. Thus, if agents behave in an obviously irrational fashion, they are said to be subjectively rational – as when they play the lottery. And if people are altruistic, it will be argued that altruism is nothing but enlightened self-interest. Being impregnable to empirical data, such models are unscientific. However, some rational choice hypotheses, notably the maximizing postulate, are testable, and as a matter of fact they have been falsified by some experimental economists.

Empiricism

Empiricism is the view that only empirical data count: that they are the source, content, and final judges of ideas. Note that the emphasis is on data (reports on observable facts), not on objective facts. So much so, that the logical positivists disallow all talk of objective facts as metaphysical, in going beyond experience. However, empiricism is not limited to positivist philosophers. Behaviorism is a prime example of empiricism, since it deliberately avoids the neural springs of behavior and it eschews theorizing. Ethnomethodology, although ostensibly tributary to the antiempiricist philosophies of Dilthey and Husserl, is another instance of empiricism, because all its practitioners do is to record overt everyday behavior.

Empiricism condemns students to the shallowness characteristic of common sense, because the most interesting facts of any kind are invisible, whence they must be guessed. For example, we can see a status indicator but not status, let alone class; and we can hear political talks, but not the interests that they manifest or disguise. Only serious sociological theory, such as that of Merton and Coleman, can suggest the search for social data that indicate social process, in particular the mechanisms behind appearances. By banning theory, or restricting it to correlating commonsense data, empiricism curtails experience. Moreover, its limitation has elicited some of the postmodern attacks upon science.

Scientific Realism

Scientific realism, or objectivism, has two components: the ontological thesis that the world outside the student exists on its own, and the epistemological thesis that it can be known. As applied to sociology, scientific realism is the view that – as Durkheim put it – social facts are just as real as physical facts, and that they can be known by blending theory with observation, measurement, and (whenever possible) experiment as well. Such knowledge is objective, but partial and gradual. In the case of social facts, research must include not only the facts themselves but also the way the actors perceive them – for example, the fact that people gauge social inequalities, and react to them, by reference to the adjoining social group.

Although scientific realism demands that theories be ultimately justified by data, it does not stifle the sociological imagination the way empiricism does. Indeed, a realist concedes that, just as some data trigger the curiosity of the theorist, at other times untested theories motivate the search for pertinent empirical data. And on still other occasions, advances come from the confrontation of either rival theories or mutually incompatible data. In short, according to scientific realism, theorizing and empirical research should go hand in hand, now matching, now challenging one another.

On the critical side, scientific realists will ask hermeneuticists (interpretivists) and other armchair students to exhibit empirical evidence for their 'interpretations' (hypotheses). They will ask rational choice theorists to specify and justify the utility functions they impute to people. They will remind Marxists and other 'economic imperialists' that real people engage in some activities that are economically unproductive or even counterproductive, and that many a social change – such as the diffusion of the computer and the revival of religious fundamentalism – has come about with little or no class struggle.

Methodology: Social Research Strategy

Methodology is the normative or prescriptive branch of epistemology: it attempts to lay down, justify, refine, or criticize research rules and procedures. Philosophers are interested only in general or cross-disciplinary strategic principles; they leave the special techniques to specialists. Here is a tiny random sample of the class of general methodological problems: How are causation and statistical correlation related? What is a social indicator? How does one infer intention from behavior? Can every social feature be quantified, or are there irreducibly qualitative properties? Is an ideographic (or particularistic) science possible? Here we will review only three rival research strategies.

Dataism: Collect Data

Social research is often equated with data hunting, gathering, and processing, whereas theory is regarded as mere data compression (as in curve fitting), or even as parasitic upon data collection. To be sure, there is no factual (or empirical) science without empirical data. But data alone do not comprise science, because they are what calls for explanation. To understand a bit of the world is to explain it. And explaining involves guessing (and then checking) mechanisms – causal, random, intentional, or hybrid. Hence, theorizing is just as important as data collecting, whether in sociology or in any other factual science. Moreover, only theory, by suggesting interesting variables and their interrelations, can spare us the barrenness and boredom of mindless data gathering.

Interpretivism: Impute Intention

The hemeneutic or interpretivist school holds, rightly, that we can explain an agent's behavior if we know the agent's intentions. But it overlooks the fact that we only have direct access to behavior, not to intentions. That is, the hemeneuticist is faced with the inverse problem of guessing intentions from actions. (Typically, inverse problems are insoluble or have multiple solutions. Think, for example, of the problem of decomposing a given even number into prime numbers, as opposed to the problem of adding prime numbers.) The hermeneuticist is entitled to guess anything, but not to present these guesses (hypotheses) as true unless they have passed suitable empirical tests. The imputation of intentions is not only dicey, it is also insufficient, because intentions, even if known, may explain success but not failure. The social constraints upon agency, and the reactions of other people to one's actions, also must be studied. That is, individuals must be placed in their systems.

Scientism: Gather Data and Craft Theory Consistent with Data

Scientism, first proposed by Condorcet and practiced by Durkheim, is the thesis that the scientific approach is the best of all approaches to cognitive problems of all kinds in all fields. Scientism should not be mistaken for naturalism, or the thesis that the social world is a fragment of nature, and consequently social research should be conducted in exactly the same manner as the study of nature. One may admit that everything social is made, while holding that, once made, a social item is out there, along with rivers and butterflies. That is, social reality is constructed, but not by the knower. And it is changeable, but not because the knowers change their viewpoint. Scientism does not involve the denial of the specificity and irreducibility of the social. It only holds that the scientific method is applicable across all of the disciplinary borders, and hence that it is advisable to trespass them whenever they are artificial. In the case of sociology, scientism favors its close relations with all its sister disciplines, particularly economics, political science, and historiography. Scientism also promotes the proliferation of social indicators, the production and statistical processing of data, and the crafting of empirically testable theories – in particular, 'middle-range' theories and mathematical models.

Hundreds of social indicators have been invented, measured, and used since the mid-1960s, and a whole journal devoted to them has been in existence since 1974. However, their very nature is still somewhat unclear, due to insufficient philosophical investigation. A social indicator bridges the observed to the unobserved, effects to causes, symptoms to mechanisms, and data to hypotheses. However, it does so ambiguously unless it can be shown that no other unobserved trait or event could possibly account for the data. For example, the popularity of low-cost merchandise may measure either consumer satisfaction or poverty; and frequent church attendance may measure either religiosity or the need for social integration (or for respectability). Ambiguity is typical of empirical indicators. By contrast, the indicators used in the more advanced sciences are unambiguous because they are backed by theories. For example, pH is a reliable measure of acidity because it is an index of proton concentration, and theory defines acids as proton donors. The moral for sociology is that the reliability of a social indicator can be increased either by grounding it in a theory or by using it jointly with other indicators of the same hidden trait.

Values and morals would seem to defy scientific realism. After all, Weber held that science ought to be value-free and morally neutral because he wished to preserve objectivity as well as the difference between science and ideology. Now, it is certainly correct to distinguish value judgments from factual statements. But not all values are subjective: some, such as peace, welfare, and truth, are not a matter of taste. Moreover, it is possible to investigate scientifically how values and moral norms emerge, and why some of them have become obsolete. It may even be argued that there are moral facts, such as misery and torture, and consequently that some moral judgments can be justified scientifically. Example: 'Anomie is wrong because it is personally and socially erosive.' It is also correct to distinguish science from ideology. Social scientists endeavor to understand social reality, not to alter it. However, some of their findings can be used by social activists, politicians, and managers to alter social conditions in a rational fashion rather than through costly improvisation. That is, a scientific ideology – one based on social science and empirically testable – is not out of the question.

The Sociology–Epistemology Connection

The traditional view of the relation between science and philosophy is that they are disjoint or even mutually incompatible. This view is mistaken, because science teems with philosophical concepts, such as those of reality, law, knowledge, and value, and because scientific research presupposes the reality and knowability of the world – a philosophical thesis. In short, philosophy and science, in particular social science, overlap partially. This overlap is only partial because only philosophers analyze philosophical constructs, and only scientists are equipped to study social facts.

However, not all philosophies are congenial with science. Whereas some philosophies are extraneous to science, others are relevant to it. For example, phenomenology is

extraneous to science because it rejects the scientific method and consists in egology, or the self-study of the self. Existentialism is even more alien, because it also rejects rationality and does not deal at all with problems of knowledge. The philosophies congenial with science examine, among other things, the problems, concepts, hypotheses, and methods common to science and epistemology. Hence, they can be judged to be pertinent and suitable to science, to the extent that they propose true accounts of actual scientific practice and help advance science. For example, Popper's philosophy is congenial with science because of its rationalism and objectivism. But his devaluation of confirmation is incompatible with the search for truth, since a hypothesis can only be said to be true to some extent if it has been well confirmed.

Sociology of Epistemology

The sociology of philosophy is only embryonic and mostly speculative. In particular, little is known about the social roots of the various epistemologies of sociology. For one thing, it is not true that they are motivated by class interests. Nor is it true that all idealists are reactionary and all materialists progressive. For example, Hegel's followers split into a left wing and a right wing. The second Comte inspired both the Mexican conservatives led by Porfirio Díaz and their contemporary Brazilian progressives.

What is true is that, once crafted for whatever reasons, some philosophical views favor certain social groups rather than others. For instance, radical skepticism, even while revolting against the establishment, objectively favors the latter in that it discourages scientific social research and therefore reasoned and well-organized opposition. Individualist philosophies favor anarchism and neoliberalism. By contrast, holistic philosophies jibe with communitarianism and totalitarianism. In short, some philosophies, particularly if fuzzy, can craftily be interpreted to suit anyone's political interests. But the more abstract philosophical ideas – in particular the logical and semantic ones – are socially neutral. Thus, neither the logical calculi nor the theories of (semantic) meaning and truth refer to social facts, whence they can neither support nor undermine any social ideology. However, they are useful to examine the cogency of any views whatsoever, and to this extent they have a subversive potential.

Abstract

The development of sociology is rarely analyzed from a sociological point of view, using the insights, concepts, and methods of the discipline itself. The most common historical reconstructions are textbook histories, written for pedagogical purposes presenting the canonical figures in a more or less chronological order. In the absence of a standard sociological account, the development of the discipline may be conveniently regarded as a long-term process structured by five major stages: a long predisciplinary stage up to 1830, marked by what in retrospect may be recognized as proto-sociologies; the formation of an intellectual discipline, both as an idea and an ideal (1830–90); the formation of an academic discipline with diverging national traditions (1890–1930); the establishment of a fully fledged academic discipline (with autonomous degrees, departments, research facilities); and an emerging international hierarchy (1930–70); and a period of crisis and fragmentation, attempts at new synthesis, and globalization (1970–present).

The standard way in which surveys of the history of sociology are written and taught still lags behind actual developments in the field itself. The writing and teaching of the history of sociology continue to be strongly dominated by the tradition of the history of ideas. Only fairly recently have some major attempts been made to view the history of sociology from a sociological angle, using sociological concepts, methods, and theories.

In the absence of a standard *sociological* survey of the development of sociology, we shall in this outline mainly follow the familiar textbook trajectory. This approach inevitably implies distortions. It suggests a pattern of Whig history, in which the history of sociology is made into a neat succession of successes. To balance that bias, the reader should bear in mind that the development of sociology itself has been a social and cultural process, consisting of a multitude of short-term planned actions and interactions with aggregate results that in the long term have not been planned by any single individual. This process took place, moreover, as a part of wider social and cultural developments.

The context was primarily European and, since the second half of the nineteenth century, North American; yet, as Europe and North America belonged to a more encompassing global constellation, we should also consider other traditions of thought and the relevance of the processes of colonization and decolonization affecting nineteenth- and twentieth-century society and culture all over the world. Much of this work, however, for such a broader view of the discipline's development remains to be done.

Sociology, furthermore, was one of the social sciences amid other intellectual disciplines: academic disciplines ranging from physics and biology to history and philosophy, as well as non-academic disciplines including journalism, political debate, and literature. Sociology took on an articulate form in continuous dialogue with those other disciplines, sometimes borrowing ideas from them, sometimes opposing them. Most of the controversies within sociology itself reflected its relations to the larger field of intellectual activities. This would be true of the moral or political views informing sociological theories as well as of the preference for either quantitative, 'scientific' methods or a qualitative, 'hermeneutic' approach (Lepenies, 1988).

In addition to the differentiation into (1) theoretical and methodological orientations, sociology has also become differentiated according to (2) empirical specializations, and (3) national traditions. These various forms of differentiation are respectively related to (1) the prevailing orientation to other intellectual disciplines, including science, philosophy, literature, and journalism; (2) the general process of differentiation of functions in society at large; and (3) international relations. While the variety of empirical specializations and national traditions is easily visible, this is not so clearly the case with the way the national traditions are 'nested' in an evolving international constellation characterized by specific hierarchies, loyalties, and corresponding intellectual interests.

We shall not continuously refer to the more general conditions affecting sociology in the following account which, because of its encyclopedic format, is written in accordance with standard practice. The reader should realize, however, that these conditions are relevant to each of the five major stages into which the development of sociology can conveniently be divided:

1. A long 'predisciplinary' stage up to 1830, marked by what in retrospect may be recognized as 'proto-sociologies'.
2. The formation of an intellectual discipline, both as an idea and an ideal, 1830–90.
3. The formation of an actual academic discipline with diverging national traditions, 1890–1930.
4. The establishment as a fully fledged academic discipline with autonomous degrees, departments, and research facilities and an emerging international hierarchy, 1930–70.
5. A period of crisis and fragmentation, attempts at new synthesis, and globalization, 1970–present.

In discussing the successive stages, we shall have to observe a basic rule of 'phaseology' (Goudsblom et al., 1996: pp. 15–30): when a later phase begins, new elements are added to the previous constellation; but most of the elements which

were already present in the earlier phase will continue to exist, albeit in a modified and less conspicuous guise.

The Predisciplinary Stage

By a discipline we mean a "unit of teaching, research and professional organization" (Heilbron, 1995). There is a body of knowledge, recognized as such under a generally accepted name, laid down in textbooks and discussed in professional journals by practitioners.

All of these elements were absent from the field of sociology prior to the nineteenth century. Yet we can list many names of people who may, arguably, be regarded as predecessors, 'proto-sociologists': people who reflected about social phenomena, collected data about social life, or tried to find patterns in human history. Some individual contributors to these traditions have gained great renown in their own cultures. Thus, from ancient Greece, the names of such men as Herodotus, Plato, Thucydides, and Aristotle stand out. Although they have been 'appropriated' as founding fathers by the practitioners of the established academic disciplines of philosophy and history, many of the problems they addressed lay in the area of what was later to become sociology. Chinese, Indian, and Arab culture have similar intellectual traditions; here, too, a few individuals have become the famous exponents of those traditions (Collins, 1998).

In this brief survey, we shall be able to pursue only the Western line leading up to the emergence of sociology as an intellectual discipline in Western Europe and North America in the nineteenth and twentieth centuries. Since the Middle Ages, there was, on the one hand, a strong tradition of philosophizing about human social life, mainly in theological and moral-legal terms, and, on the other hand, an increasingly strong tradition of collecting facts, most often related to state matters and focused on knowledge of the population and its resources, both at home and abroad (as reported by explorers and travellers). By and large, the two traditions stood apart.

The transition from the predisciplinary stage to the actual conception of sociology as an intellectual discipline in its own right occurred in the eighteenth and nineteenth centuries. The shift consisted partly in conscious attempts to bridge the gap between theory and empirical inquiry, between philosophical reflection and the collection of facts about social life. The leading intellectual model, furthermore, was sought no longer in theology or metaphysics but in empirical science. Insofar as the focus had been either on the political realm or on more 'private' moral issues, it now moved to the structure and development of 'society' at large. This threefold shift in orientation was pioneered by the groups which have become known as the French *philosophes* and the Scottish moral philosophers. Their work was developed in different directions during the last decades of the eighteenth and the first decades of the nineteenth century.

Among the *philosophes*, Montesquieu was one of the first and most influential. He demonstrated that types of government are to be understood in relation to their moral and physical infrastructure. For an understanding of such connections, a recognition of the 'general spirit' of a nation is central. This 'spirit' or 'common character' results from the combined effect of various causes, including climate, religion, and commerce. Instead of drawing deductions from an original principle such as a political or social contract, Montesquieu thus started to unravel the complex interdependencies of human society.

While Montesquieu pioneered the study of what Auguste Comte later was to call 'social statics', his younger contemporary, the future statesman Turgot pointed to the possibility of also viewing human society from a developmental perspective, in other words, in terms of 'social dynamics'. That idea was further elaborated in theories of successive stages or phases by such writers as Condorcet and Henri de Saint-Simon.

In a kindred spirit, the Scottish moral philosopher David Hume proposed introducing "the experimental method of reasoning into moral subjects". Hume and his younger friend Adam Smith rejected theories based on an assumed state of nature. Such reasoning had characterized the natural law tradition – the predominant framework for early modern theories of government and moral obligation (Grotius, Hobbes, Locke, Pufendorf). For Hume, the state of nature was a hypothetical construct, incompatible with the precepts of empirical science. To consider states as the result of an original voluntary act of agreement was illusory and contrary to scientific procedure. Social institutions, in Adam Ferguson's famous phrase, "are the result of human actions, but not the execution of any human design". From this perspective, morality would have to be studied historically and comparatively, tracing its development through the successive stages of hunting, shepherding, agriculture, and commerce.

As the idea of a general social science gained ground, various attempts were made to connect that idea to existing scholarly disciplines. Some groups, particularly in France, pursued the ideal of a social science modeled after the natural sciences. Thus, by applying probability theory to voting procedures and judicial decision making, mathematicians such as Condorcet and Laplace proposed a 'social mathematics'.

British liberal thinkers such as Jeremy Bentham and James Mill somewhat similarly tried to build a social and political theory upon the idea of a moral arithmetic. Individuals and governments alike should promote the amount of happiness and reduce the amount of pain. Their felicific calculus, aimed at the greatest happiness of the greatest number, provided the means for assessing the utility of public institutions. Others, such as Saint-Simon, couched their analysis of early industrial society in a medical idiom advocating a 'social physiology'. Conservative social theorists such as Edmund Burke, Joseph de Maistre, and Louis de Bonald, by contrast, while recognizing the reality of 'social relations' and 'society', opposed the notion of a natural science of society, and rather sought inspiration in theology, philosophy, and history.

The Formation of an Intellectual Discipline (1830–90)

In the course of the nineteenth century, empirical social research became a regular and organized endeavor. Most of it was centered on the 'social question' and intimately linked with governmental agencies and reform movements. Besides a multitude of local initiatives, national associations arose for the coordination of these efforts: the French *Académie des sciences morales et politiques* (1832), the English *National*

Association for the Promotion of Social Science (1857), the *American Social Science Association* (1867), and the German *Verein für Socialpolitik* (1873). More theoretically informed work made use of the research findings, but was carried out mainly by individual scholars who either possessed private means or made a living by writing and lecturing. Thus, Auguste Comte, John Stuart Mill, and Herbert Spencer were for most of their professional lives publicists, men of letters with a strong interest in the sciences. All three contributed significantly to the formation of sociology as an emerging discipline, but none of them was a regular academic or was actively involved in social research.

Other writers, such as Alexis de Tocqueville, Karl Marx, and Adolphe Quetelet, shared similar interests, but consciously avoided the term sociology. Marx and Tocqueville have been incorporated in the canon of the discipline only after 1945. While Tocqueville called for a 'new political science for a new world', Marx' critique of political economy resulted in a theory of capitalism and class domination. The Belgian astronomer and statistician Quetelet continued the efforts of Condorcet and Laplace. He considered the ever growing body of statistics to be the proper basis for a 'social physics'.

When Comte publicly introduced the term sociology (the word had previously been used in an unpublished manuscript of the French revolutionary publicist Sieyès), he was likewise concerned with the idea of a fundamental science of human society. At the time, Comte had no interest in applied knowledge, rejected premature specialization, and wanted to construct an appropriate foundation for social science. The term sociology captured all of these ambitions quite well. It conveyed the idea of a positive science, suggesting both a high level of generality and a great degree of independence from the natural sciences. For Comte, sociology was to become an uncompromising positive science but should not be conceived of in terms of either physics or physiology. Instead, sociology was to biology what biology was to physics: a relatively autonomous science with its own subject matter and mode of conceptualization.

In the *Cours de philosophie positive* (1830–42), Comte explained that different methods prevail in the various sciences: the experimental method in physics, the comparative method in biology, and the historical method in sociology. Sociology had to be founded on a historical law. Since human beings specifically have the capacity to learn, the development of knowledge is the core of human development, and Comte considered his law of the three stages in the development of knowledge as the proper point of departure for sociology.

Comte's plea for sociology as the general social science was well received in England, first in the circle of John Stuart Mill, then by Herbert Spencer. Mill rejected Comte's criticisms of psychology and political economy, but admired his philosophy of science and embraced the idea of sociology. Yet, like the French followers of Comte, Mill never wrote a properly sociological study. One of the first sociological treatises appeared in the 1870s and was written by Spencer – the most widely read sociologist of the nineteenth century.

For Spencer, progressive change was the common denominator of all natural processes. From the maturation of an embryo to the evolution of life in general, all living things evolve from the simple to the complex through successive differentiation and integration. Evolution is the natural process of change from incoherent homogeneity to coherent heterogeneity. Human societies are no exception: they too develop through differentiation, a process steadily accompanied by higher levels of integration and coordination.

Spencer's view of evolution was thus broader in scope than both Comte's sociological and Darwin's biological theory. Combining a laissez-faire view borrowed from economics with an embryological model of growth, Spencer gave the evolutionary principle the status of a universal law and made it the core of his all-embracing system of synthetic philosophy. As stated in his influential essay 'The Social Organism' (1860), Spencer's sociology was cast in the organic idiom, while carefully maintaining an individualist perspective. In *Principles of Sociology* (1876–97) he elaborated his analysis, emphasizing the passage from 'militant' to 'industrial society'. In the latter, social integration is no longer imposed from a controlling center, but the spontaneous result of individuals who cooperate on the basis of a division of labor. Spencer strongly favored a laissez-faire stance, opposing state politics (in matters of welfare as well as in colonial expansion), and inspired what was – inaccurately – called social Darwinism.

His position as a freelance writer and lecturer allowed Spencer to make virtually unlimited claims for the scope of sociology. While he was most outspoken and influential in articulating the idea of sociology as an intellectual superstructure sustained by an evolutionary perspective and overarching all the other social sciences, that idea was shared by several other leading advocates of sociology in Europe and the United States.

The Formation of an Academic Discipline, 1890–1930

Sociology as an academic discipline sociology emerged between 1890 and 1930. The first courses and chairs were established, sociological journals appeared as the primary outlet for research; and sociological associations were founded for furthering intellectual exchange and professional interest. France, England, Germany, and the United States were the core countries, and in all of them distinct national traditions took shape.

Wherever sociologists managed to obtain a position in the academic world, they had to accommodate to the constraints of established institutional divisions. The realm of law was the domain of the legal profession. The study of the past was already successfully claimed by the historians. In a similar vein, psychologists succeeded in monopolizing individual development and behavior as their field of expertise, economists specialized in the economy, anthropologists in the structure and culture of nonliterate societies. Sociologists had little choice but to accept this division of academic labor as a social fact; this left a strong mark on the way they conceived of their own discipline.

Emile Durkheim was the pivotal figure in French sociology. He taught his first course in 1887, wrote classic works on the division of labor, suicide, and the rules of sociological method in the 1890s, and organized a network of highly productive scholars around his journal, the *Année sociologique* (1898–1912). By proclaiming that social facts had to be

explained by other social facts, Durkheim broke away from the predominant biologistic and psychological approaches. His explanation for variations in the suicide rate was a paradigmatic example. The social realm was a reality *sui generis* with its own structure and regularities. Systems of collective representations are an essential part of social life, not merely when studying religion or morality, but also for understanding the economy and political institutions. Following this line of argument, Durkheim and his collaborators (Marcel Mauss, Henri Hubert, Marcel Granet, Maurice Halbwachs, François Simiand) worked on a wide range of topics, contributing to many fields outside of sociology proper.

In England, sociology did not gain a proper entry into the university system until well after the Second World War. The rich tradition of factual inquiry was continued by government officials and wealthy individuals (Charles Booth, B.S. Rowntree), but remained almost entirely separated from academia. Despite the existence of a sociological journal and a professional association, the British academic establishment did not show much interest in sociology. The only chair for a long time had been established in 1907 for L.T. Hobhouse, who, in 1929, was succeeded by his pupil Morris Ginsburg. Both men maintained a cautious evolutionary perspective but neither one built up a network of productive scholars. Whereas British academics showed little interest in studying their own society, they had no such inhibition about studying the exotic regions of the British Empire. Social anthropology became a respected academic discipline and partly served as a substitute for sociological concerns.

Sociology in Germany emerged later than in France and England; a professional association was founded in 1910, a first chair in 1917, and a journal in 1921. The academic pioneers in Germany, men like Ferdinand Tönnies, Georg Simmel, and Max Weber, faced two powerful indigenous traditions. The oldest was that of the *Staatswissenschaften*. The proponents of these disciplines (law, economics, public administration) consistently subsumed civil society to the various functions of the state. This mode of thinking had its roots in eighteenth-century cameralism and was refashioned in the nineteenth century by idealist philosophers such as Hegel. After the founding of the German Empire, the members of the *Verein für Socialpolitik* maintained much of this conception of social science. They were opposed by liberal economists like Carl Menger during the first *Methodenstreit* in the 1880s and 1890s and by Max Weber and others during the second *Methodenstreit* in the decade prior to the First World War. An important aim in Weber's argument about the value-freedom of scientific inquiry was to create a greater distance from the practice of the state sciences.

The other tradition with which German sociologists grappled was the persistent opposition of the natural versus the cultural sciences: the former were supposed to be concerned with causal explanation, the latter with interpretative or 'hermeneutic' understanding. Early sociologists such as Comte and Spencer had often been rejected in Germany as representatives of an inadequately naturalistic conception of the human sciences. Reflecting on these epistemological issues, Max Weber proposed to transcend the dichotomy by ingeniously defining sociology as the science of social action, which by interpretative *understanding* seeks to *explain* its course and consequences.

Weber was nominated for a chair in sociology shortly before his death in 1920. His achievements and those of others of his generation (Simmel, Alfred Vierkandt, Werner Sombart, Franz Oppenheimer) contributed to the recognition of sociology as an academic discipline during the Weimar Republic (1919–33). Sociology expanded rapidly, opening opportunities for a generation of young scholars including Max Horkheimer, Theodor Adorno, Theodor Geiger, Karl Mannheim, and Norbert Elias. Although all these men had initially received a training in different academic fields, they were ready for brilliant careers in sociology. However, the seizure of state power by the National Socialist Party in 1933 made an abrupt end to the favorable outlooks for German sociology, forcing all these scholars along with many of their colleagues into exile.

Sociology's most rapid expansion took place in the United States. The first courses were taught in the 1870s and 1880s, while the expansion of higher education in the 1890s furthered a quick institutionalization. Within two decades, sociology was taught in most colleges and universities; textbooks standardized the concepts and methods of the new discipline.

American sociology developed primarily on the basis of empirical research into current social problems. The main topics were the issues which were widely debated by politicians, religious leaders, and social reformers: massive immigration, urbanization, industrialization, local communities, social (des)integration, and ethnic and race relations. Empirical studies proliferated, based either on statistical material or on actual fieldwork.

By the 1920s, the sociology department in Chicago, founded by Albion Small in 1893, had become the predominant center. Small also played a key role in the *American Journal of Sociology* (1895) and, together with George E. Vincent, wrote the most widely used textbook, *An Introduction to the Study of Society* (1894). The work of the Chicago School was founded on qualitative case studies, using observations, interviews, and life histories. Exemplary were William I. Thomas and Florian Znaniecki's *The Polish Peasant* (1918) and the collective volume on *The City* (1925).

Parallel to the entry of sociology into various national academic systems, the French sociologist René Worms founded an international association, the *Institut international de sociologie* (1893), and an associated journal, the *Revue internationale de sociologie* (1893). Worms brought together a considerable number of the best known European and North American sociologists; the major exception being his French competitors around Emile Durkheim (Fleck, 2011). The membership of his International institute, which held 13 international congresses between 1893 and 1937, included many nonacademic dignitaries, as well as numerous scholars from other disciplines, such as law and economics, and the focus of the meetings was more on the discussion of general themes than on the advancement of research. The limited significance of this incipient internationalization is well illustrated by the fact that the two most important sociologists, Durkheim and Weber, never met one another nor did they ever refer to each other's writings.

Establishment as an Academic Discipline, 1930–70

Between 1930 and 1970, sociology became established as an academic field at most universities in the Western world. The number of practitioners and students greatly increased, and

there was a proliferation of specializations in research and teaching. Far from being an even process of growth all over, however, these trends were marked by far-reaching structural changes: a severe break down in the development of sociology in Europe and a concomitant shift of intellectual leadership in the field from Europe to the United States.

The leaders of the first generation of American academic sociologists all acknowledged an intellectual debt to European masters. Even in the early 1920s, it was still not uncommon for a promising American social scientist to start his career with a European apprenticeship, as did Talcott Parsons who went to London and Heidelberg. At the time, however, the westward exodus of sociologists from Eastern Europe was already underway, as the communist regime in Russia and the fascist regime in Hungary tightened their grip, greatly restricting the margins for sociological inquiry and reflection. The year 1933 brought the decisive rupture: the seizure of power by the Nazis in Germany put an end to the flourishing sociology of the Weimar Republic and forced a great number of prominent and promising sociologists into exile, mostly to the United States (Fleming and Bailyn, 1969).

In contrast to Europe, sociology in the United States suffered no drastic interruptions in the years between 1933 and 1945. It remained a subject in most college curricula, with textbooks such as Park and Burgess's *Introduction to the Science of Society* (1924) continuing to supply an authoritative framework of concepts and ideas. At the same time, practically oriented research in areas of social problems and social policy was stimulated by increasingly generous funding from both government and private foundations (Platt, 1996). Empirical research received a powerful boost after 1941, when social scientists were recruited for the war effort and commissioned to study variables fostering the morale of the Armed Forces.

After 1945, the United States emerged as the major political, economic, and cultural power in the world. In the social sciences, including sociology, American examples were virtually unrivalled in setting an international standard of competence in method and theory. An impoverished Europe lacked the resources for challenging the American ascendency. The relatively autonomous sociological traditions in Germany and Italy were virtually destroyed. Sociology in England had only a minor position at the London School of Economics. In France, the Durkheimian tradition continued to exert considerable intellectual influence among anthropologists and historians, but the institutional basis for sociology as an academic discipline had seriously weakened.

Thus the scene was set for American dominance. The sociology departments at Harvard and Columbia University in particular gained international renown. At Harvard, Talcott Parsons developed a new synthesis of sociological theory, mainly derived from European predecessors, which he presented as a 'general theory of action' – although in its worldwide reception it became known as 'structural functionalism' or simply 'functionalism.' Still, Parsons' generally recognized status as the world's leading sociological theorist did not imply that his ideas put a mark on the entire discipline. There were some influential rival theorists, including his Harvard colleague George Homans who advocated a strictly scientistic 'exchange theory' inspired by the model of *homo economicus*. At Columbia, Parsons' former student Robert Merton propagated a more modest ideal of 'theories of the middle range,' which proved to be very well compatible with the work of his colleague Paul Lazarsfeld, an immigrant from Austria who specialized in the organizational and methodological aspects of social research.

The years between 1955 and 1975 in particular spelled a boom period for American sociology (Turner and Turner, 1990). The successful launching of Sputnik by the Soviets in 1957 inaugurated an era of unprecedentedly high government funding of scientific research in the United States, which also benefited sociology. In the 1960s, a combination of demographic trends (the postwar baby boom) and political discontent made for a dramatic increase in student enrollments. Professional self-confidence, which had been clearly mounting since the early 1940s, surged to new heights. The auspices were favorable for manifold activities in the realm of academic sociology: systematic elaboration of theoretical ideas in the Parsonian fashion; exploration of the possibilities of rivaling theories presented under such labels as exchange theory or symbolic interactionism; and empirical research, conducted in many forms from intensive 'qualitative' case studies to extensive quantitative surveys, and applied to a broad range of social phenomena. Sociologists in most other capitalist-democratic countries outside the United States adopted similarly diverse programs for teaching and research.

The expansion of the discipline was accompanied by more regular forms of international circulation. American foundations like the Rockefeller and the Ford Foundation supported empirical social science research, both inside and outside the US, and provided grants for studying at American universities. UNESCO initiated and funded international social science associations, among them the International Sociological Association (1949), which was founded on the basis of a small number of national organizations from the core countries. The growth of the ISA was initially assured by the increasing membership of national associations (Platt, 1998). In spite of the Cold War but in line with the UNESCO policy to promote international understanding, national associations from several Communist countries in Eastern Europe joined in the late 1950s. In the course of the 1960s and 1970s, membership increased further by allowing individuals and associate members to join, thus breaking away from the United Nations model of national representation. Among the associate members were regional organizations from Europe, Latin America, and Asia. As the meetings of the International Sociological Association testified, by the end of the 1960s sociology was a blooming pluralistic discipline, with a tacitly accepted hierarchy of prestige headed by American sociologists whose ideas set the agenda for the discipline at large. Unintendedly, the publication of the 17-volume *International Encyclopedia of the Social Sciences* in 1968 spelled the ending of that era.

Crisis and Fragmentation, Attempts at New Synthesis, and Globalization 1970–Present

If the years around 1970 formed a watershed in the development of sociology, the tendencies that then became manifest had been at work for some time. Mainstream academic

sociology as represented by the combination of functionalist theory and survey research rapidly lost its appeal to a new and vociferously critical generation. With much programmatic gusto, new 'paradigms' were launched, highly diverse in their implications, but all radiating the same radical spirit. Inspired by political protest movements, a culture of dissent arose in sociology, criticizing the intellectual canon and the professional stance of the discipline. The short-term result of this turmoil was the demise of functionalism as the leading theoretical perspective, and a flurry of controversies about a mixture of ideological, epistemological, and methodological issues. At a longer term, after a reaction to the surge of politicalization had taken place and the world economy was hit by a severe recession in the late 1970s, the manifest controversies receded and a state of fragmentation ensued to which most practitioners tacitly accommodated.

Fragmentation took many forms. The most obvious and least contested form was the proliferation of subdisciplines around an unsystematic array of specific research areas such as the sociology of the family, organizations, and culture. Then, equally noticeable but far more controversial, there was a plurality of theoretical orientations, often with corresponding methodological presumptions. Some theories were primarily attuned to specific forms of microsociology, marked by an affinity to various philosophic schools ranging from phenomenology (embraced by ethnomethodologists), through pragmatism (preferred by symbolic interactionists), to neo-positivism (for rational choice theorists). Network analysis emerged out of the study of microinteractions as well, but it developed into a set of techniques and ideas that could be applied at any level of aggregation. In the realm of macrosociology, functionalism as a perspective gave way to new approaches influenced by Marxism and emphasizing social conflict and long-term social transformations. Fragmentation was further enhanced by a weakening of the hierarchy in the international sociological community, growing geographical diversity, and an increased articulation of national traditions.

None of these changes came out of the blue; but together they produced an almost revolutionary shock to the world of sociology. Whereas the most famous sociologists of the previous generation had all been Americans, now European names again came to the fore: Michel Foucault, Pierre Bourdieu, Anthony Giddens, Jürgen Habermas, and somewhat later, Zygmunt Bauman, Ulrich Beck, and Manuel Castells. During the early 1970s, while many older sociologists deplored the patent end to the illusion of consensus in the discipline, there was also a widespread sense of excitement over new intellectual possibilities and career opportunities. Ideological debates around many current topics, from gender and race relations to the reform of psychiatry, were saturated with sociological references.

The later 1970s saw a dramatic reversal in this mood of confidence. General public interest turned away from sociology, student enrollments dropped rapidly, and research funds shrank – the only sediment of the earlier high tide that remained was internal fragmentation and pluralism. The general stagnation at first reinforced the tendencies toward fragmentation, as established subdisciplines tried to maintain their position in the face of diminishing institutional support for, and intellectual vigor of the sociological discipline as a whole. However, the 1980s and 1990s also brought new attempts toward a synthesis. Thus, in historical and comparative sociology the orthodox Marxist approach tended to be softened by combining it with a more liberal Weberian perspective. 'World systems' theory as originally developed by Andre Gunder Frank and Immanuel Wallerstein helped to break away from the implicit focus on the national state that characterized most sociological work during the preceding stage. Making the transnational order, conceived either as a world system, or alternatively as 'transnational society,' into the centrepiece for sociological study gave counterweight to the tendencies toward national parochialism. After the collapse of communism and parallel to the rapid development of computer technology and the internet, globalization became a key area of debate and research. It soon proved a challenge to the organization of the discipline as well. At the beginning of the twenty-first century, sociology is practiced in virtually every country and region around the world, levels of transnational communication and collaboration are rapidly rising, and English has become the language of global social science. While much of the production of articles and books remains concentrated in North America and Europe, where the most prestigious journals and departments continue to be located (UNESCO, 2010), sociology's more global scope has also provoked a vivid debate about Western hegemony, indigenous traditions of thought, and the diversity of globalizing sociology (Patel, 2010).

Other ventures in historical and comparative sociology have sought synthesis in a different direction. During the 1980s and 1990s, Randall Collins valiantly subjected a wide range of long-term cultural trends (including religion and philosophy as well as technology) to sociological analysis, while Jack Goldstone and Charles Tilly brought sophisticated techniques of statistical analysis to bear on huge sets of historical data. Meanwhile Norbert Elias's work, aiming at a thorough integration of sociology with history and psychoanalysis, was gaining influence inside and beyond the discipline.

These promising signs could not hide the fact, however, that after decades of rapid growth in the 1960s and 1970s, sociology had entered a period of less favorable circumstances. The welfare state came under siege in many Western countries, and neo-liberal policies in favor of deregulating and extending markets gained the upper hand. Even if the collapse of the Soviet empire and the termination of the Cold War have not spelled 'the end of history', these events did lessen interest in ideological matters and theories of society.

At the universities, the established social science disciplines (economics, sociology, anthropology, political science) have faced increasing competition from new multidisciplinary fields of study, which are more immediately focused on policy needs (organizational studies, management, business) or the demands of particular student groups ('Black studies', gender studies). The strains of the present situation are also conducive to a revival of the old polarity between 'scientistic' and 'humanistic' approaches. Provocative challenges to the social sciences have come from sociobiology and the neurosciences, while the scientistic posture gave a great deal of prestige to 'rational choice' models by means of which assumptions and

methods derived from economics are applied to a wide array of non-economic relations. Resisting the invasion of economics, other sociologists advocated an opposite move, to resubmit economic processes and institutions to sociological scrutiny and redevelop economic sociology. Ironically, the humanistic approach is posing a similar risk: embracing culturalistic and postmodern ideas, drawn mainly from current anthropology, literary studies, and hermeneutic philosophy, may also detract sociologists from the core of their discipline – the study of social processes and social structures.

The opposing social currents at work in the world today, as well as the more directly felt institutional pressures and intellectual challenges are confronting sociology with a variety of contradictory claims. Recognizing the many sources of confusion is a first requisite in order to arrive at a balanced response to this situation. Equally important for a more reflexive sociological practice is a continuous reconsideration of the history of the discipline.

Abstract

Scholars of sociology, commonly defined as the scientific study of social relations, social institutions, and societies, conceive the objectives, uses, styles, and methods of their discipline in various ways. One type of sociologist grants it primarily an informative function, that of producing data and analyses to aid decision makers. A second type sees it as serving a critical function, that of identifying the various defects of societies. Finally, a third type sees sociology as a means of explaining social phenomena. These three orientations characterize contemporary as well as classical sociology. Sociologists also endorse a range of methodological and theoretical positions. While some oppose a positivist to an antipositivist approach, others oppose a holistic to an individualistic stance, a rational to an irrational theory of behavior, or a utilitarian to a nonutilitarian view of rationality. Max Weber's sociology is of particular value, for it offers a paradigm capable of transcending these alternatives. One may effectively refute the skepticism that has developed toward sociology and its variety of approaches by focusing on its genuine achievements and demonstrating how actual research has overcome theoretical oppositions in various cases.

The institutionalization of sociology followed a long and circuitous path. The actual term was coined by Auguste Comte and institutionalized in periodicals. The existence of sociology was also recognized implicitly, however. When, in the very first sentence of *The Old Regime and the Revolution*, Alexis de Tocqueville (1986[1856]) wrote "[t]his book is not a book of history," he meant that it dealt with what we would today call 'comparative sociology.' He did not use a word that was still uncommon and probably even considered Comte an eccentric figure. Weber too expressed doubts as to whether his work should be classified as sociology. The gradual institutionalization of the term and discipline owes much to Émile Durkheim and later, the Chicago school of sociology.

Sociology: A Unique or Multiple Discipline?

Despite being contemporaries and able to read each other's works, Durkheim never quoted Weber, nor Weber Durkheim. All the same, as Nisbet (1966) maintains, common inspiration can be detected in the works of Tocqueville, Karl Marx, Georg Simmel, Weber, Vilfredo Pareto, and Durkheim. All appear to agree that the rational utopian theory of society developed by the Enlightenment was unacceptable. Consequently all perceived the social functions of religion, the hierarchical distinctions between social ranks, the role of tradition, and the distinction between 'community' and 'society.'

Describing the identity of classical, and, even more, modern sociology can be more difficult than Nisbet proposes, for both classical and modern sociologists see very different uses for sociology and the ways in which it should be practiced.

Three Types of Objectives

The first type of sociologist sees the discipline as having an essentially *informative* function, however – that of producing data and analyses oriented implicitly and explicitly toward decision makers. Thus, in *Les ouvriers européens* (1855), Frédéric Le Play surveyed the conditions of life among European workers with the final objective of improving the social policies of the time. While the workers themselves would have known about their lives, this local knowledge was not directly available to societal decision makers. Collecting statistics related to crime is another example of sociology's informative function. Such data are crucial to the determination of crime policy. Gabriel Tarde, for example, became a sociologist because, as a judge and later as the head of the French Bureau of Statistics on Crime, he was concerned with an increase in crime rates. Joseph Schumpeter qualified the informative dimension of the social sciences as 'cameral' (*Kameralwissenschaften*). In the 1970s, Paul Lazarsfeld et al. (1967) offered an overview of the production of this 'cameral' sociology in the *Uses of Sociology*.

The second type of sociologist sees the function of sociology as *critical*, that of identifying the defects of actual societies and devising remedies to correct them. Henri de Saint-Simon and Pierre-Joseph Proudhon are considered pioneers in this type of sociology, while members of the Frankfurt School exemplify a modern version of 'critical' sociology.

The third type of sociologist sees sociology as having the same objective as other scientific disciplines, namely, that of explaining social phenomena that appear enigmatic at first glance. Weber, for example, wondered why peasants appeared more attracted to polytheistic than monotheistic religions, while Durkheim was interested in why all religions included the notion of 'soul' in one form or another. In such cases, the interests of sociologists are essentially of a *cognitive* character.

These three basic orientations can appear in combination. Marx was concerned both with explaining social mechanisms and changing society. Durkheim gathered data on suicide with the aim to explain variations in suicide rates, but also considered them indicators of the general state of modern society. All the same, the works of de Tocqueville, Weber, and Durkheim achieved the status of 'classics' essentially because they contained scientifically valid explanations for puzzling social phenomena, rather than for their diagnoses of the society of their time. Durkheim deemed sociology as socially useful only

if it was scientifically sound, meaning that good criticism could derive only from valid explanation. In contrast to Durkheim or Weber, the Frankfurt School is better known for its criticism of modern societies than for convincing explanations of puzzling phenomena.

These three orientations characterize modern, contemporary, and classical sociology. Marcel Foucault's *Discipline and Punish* is generally recognized more a 'critical' than a 'scientific' contribution to the field (Foucault, 1975). According to the 'labeling theory,' some features of individual A can be interpreted as a 'label' by observer B and can structure B's behavior and expectations toward A. This is common knowledge, however, so the theory does not introduce anything new. Its 'critical' function is more undebatable than its cognitive one. So, the 'labeling theory' is not a theory in the scientific sense. Yet as Foucault's theory, it has had a notable influence on our views and those of public officials as to the way in which prisoners should be considered and treated.

Several Types of Orientations

Sociology is often perceived as a discipline with a weak identity, not only because of the existence of its three basically different goals, but also because those sociologists who consider the main goal of their discipline to be the production of valid new knowledge on social phenomena endorse a variety of methodological and theoretical orientations. Weber's work, for example, is seen as illustrating a particular style of 'comprehensive' sociology that is currently opposed to a 'positivist' conception of the field. While the former proposes to analyze social phenomena as the outcome of comprehensible individual actions, the latter analyzes relations between social phenomena. Weber himself considered his version of 'comprehensive' sociology as being very different from that of others, and repeatedly spoke of 'comprehensive sociology in my sense (*in meinem Sinne*).' In the 1960s, 'quantitative' and 'qualitative' sociology were perceived as irreconcilable rivals; while the former deemed the collection of standardized data capable of being subjected to statistical analysis as the most effective research procedure, the latter insisted that such an approach produced biased findings and thus proposed more flexible methods. Robert Merton's 'middle range theory,' which aimed at explaining specific social phenomena, was seen as the proper alternative to the sort of general theory on 'society' as a whole proposed by Parsons, which C. Wright Mills polemically referred to as 'Grand Theory.' These notions illustrate some of the main more or less permanent and distinguishable conceptions of sociology.

Such diversity within the basic theoretical orientations of sociology is also one of its permanent features, observable in contemporary as well as classical sociology. In the early twentieth century, a 'methodological quarrel' set those who believed that sociology should follow the path of other scientific disciplines in opposition to those who, like Heinrich Rickert, maintained that while the goal of natural sciences was 'explanation,' the goal of the social sciences was 'interpretation.' In the 1960s, the quarrel was reopened with the 'positivists,' as their challengers called them, set against the 'hermeneuticians,' who once again saw sociology as charged with disentangling the 'meaning' and 'interpreting' social phenomena rather than identifying their causes, that is, 'explaining' them. Theodore Adorno and Karl Popper, were the main protagonists of the 'antipositivist' and 'positivist' groups, respectively (Adorno et al., 1972[1969]). This 'quarrel' has reappeared chronically in various forms. Thus, not long ago, ethnomethodologists claimed that the idea of producing an objective social knowledge was self-contradictory since social phenomena were understandable only from the inside of a social group: one could interpret, but not explain them.

Weber's sociology is particularly important for it defines a third way between 'positivism' and 'antipositivism.' To Weber, explaining a phenomenon means uncovering its causes. The causes of any social phenomenon reside in the set of individual actions, beliefs, or attitudes of the individuals responsible for it. The sociologist thus has to make these individual actions, beliefs, or attitudes 'understandable.' At the same time, however, understanding an individual action requires finding the action's meaning to the actor, in other words, the motivations and reasons behind it. For Weber this operation amounts to building a theory on the motivations of social actors that is subject to the ordinary criteria that every scientific theory must meet. Thus, if I see somebody cutting wood in his yard on a hot summer day, I would reject the theory that he is cutting wood because he is cold. On the whole, Weber holds that 'understanding' is a crucial moment in the 'explanation' of any social phenomenon.

Sociologists who are mainly interested in the 'cognitive' function of their discipline, namely, in its capacity to produce valid new knowledge, can thus be classified along a first principal dimension, according to whether they see it as capable of producing '*explanations*,' in the manner of other scientific disciplines, or merely generating '*interpretations*' of an unavoidably subjective character. Here, however, one needs to introduce a secondary distinction that opposes those who, like Durkheim in his *Rules*, believe that the subjectivity of social actors should be ignored by sociologists (Durkheim, 1895), and those who, like Weber (1951), consider that the subjectivity of social actors is essential to sociological knowledge and in no way incompatible with the discipline's scientific ambitions.

This last distinction correlates with another one. Some sociologists regard individuals as the atoms of sociological analysis, while others claim that sociology should ignore individuals and concern itself with analyzing associations between social phenomena and variables. While the former follow the principles of what Schumpeter called '*methodological individualism*,' the latter preach '*methodological holism*.' Weber explicitly declares that to him, individuals are the atoms of every sociological analysis and that sociology should be 'individualistic as far as its method is concerned' (Mommsen, 1965). Durkheim, by contrast, sees sociology as devoted to the analysis of the associations between observable social variables. He offers a theoretical defense of this viewpoint in *Rules* (1895) and a practical one in *Suicide* (Durkheim, 1897).

It suffices to evoke a few modern sociological schools to see that the above distinctions, according to which classical sociological works can be categorized, can also be used for modern studies. Thus, 'structuralism' falls on the side of positivism as it proposes to identify the stable relations that prevail

between social variables and claims to be hard science; on the other hand, it is holistic, since it treats individuals as the mere products or reflections of 'structures.' 'Rational choice theorists,' in turn, propose to analyze social phenomena as the effects of individual actions; they firmly believe that sociology can be as objective and scientific as any other discipline but on the condition that it respects the postulate that social phenomena are the outcome of individual actions motivated by individual interests. 'Ethnomethodologists' believe that sociology is an interpretative rather than an explanatory discipline, but are mainly concerned with the interpretations offered by individuals who are embedded in the social setting in question. Following the footsteps of Jakob Burckhardt or Fernard Braudel, holistic sociologists of history, such as Norbert Elias or Immanuel Wallerstein, focus on detecting diffuse orientations within the course of historical and social processes. They are more concerned with the interpretation than the explanation of social phenomena and are interested mainly in identifying global macroscopic trends.

The lasting relevance of the various conceptions of sociology emerging from the typologies discussed above explains why sociology appears as less of a unitary discipline than do many others. Furthermore, the relative popularity of each of these conceptions tends to follow an 'oscillatory' process, as Pareto would have termed it. In the 1960s, many circles considered structuralism the orientation that would make the social sciences genuinely scientific. Sharply criticized, however, it became obsolete. Viewed as 'positivist' and 'holistic,' it was replaced by antipositivist and individualistic currents such as ethnomethodology or 'phenomenology' in the sociological sense.

A Few Genuine Achievements

The best way to refute those skeptical of sociology's diversity is to examine the successes of its various typologies as outlined above.

Durkheim's *Suicide* (1897) is a classical example of the holistic-positivist type of sociology. The work offers systematic analysis of correlations between rates of suicides and a number of independent variables, such as gender, urban versus rural residence, religious affiliation (Protestant, Catholic, Jew), and so forth. Through his research, Durkheim discovered that rates of suicide increase with a rise in anomie. Other things being equal, professionals are exposed to more anomie than are peasants and are thus more prone to suicide. Anomie is also greater during economic booms when expectations tend to be too optimistic and open the way to disillusion, which eventually leads to higher rates of suicide. Durkheim's *Suicide* provides a methodological model that has inspired many writers. Thus, for example, Cusson (1990) has asked why rates of criminality have been characterized by similar trends in most Western countries with the exception of Japan and Switzerland. He attributes this exception to the fact that primary social control is more developed in these two countries, where, for historical reasons, networks of interpersonal relations typical of traditional societies have been maintained even in large cities.

It should be noted, however, that though such analyses are explicitly holistic, they implicitly consider individual motivations. Thus, in *Suicide*, Durkheim contends that periods of political crises can be associated with a decline in suicide rates, and that – other things being equal – they were effectively lower during major political upheavals in France during the last two decades of the nineteenth century, as well as during the crisis between Prussia and Austria in the mid-1860s. Like other theories in *Suicide*, this one sees an association between two variables defined at the societal level, and, in this sense, is holistic. However, it rests implicitly on the 'psychological' assumption that in periods of serious political crises, people are not exclusively concerned with their personal problems. The same can be said of most of Durkheim's analyses in *Suicide*. The activity of professionals, for example, is much less routinized than that of peasants; professionals cannot be content with following the same rules of behavior day after day, but instead are always devising new rules, objectives, procedures, or ideas. The greater uncertainty generated by such novelty breeds a higher level of anxiety. So, despite his official opposition to the psychological explanation of social facts and his recommendation that social facts be explained solely by social facts – as formulated in the *Rules* – Weber's sense of 'understanding' is implicit in Durkheim's *Suicide*. Thus, according to Durkheim, women in the nineteenth century had lower rates of suicide than did men because, being more exposed to social control, they were more guided by routinized rules and norms and thus less exposed to the anxiety generated by uncertainty.

The contrast between Durkheim's holistic antipsychological sociology and Weber's individualistic approach is therefore less marked than sometimes contended. Indeed, Weber is as interested as Durkheim in macroscopic relations. In his *Essays in the Sociology of Religion*, for example, he notes that Mithraism developed among Roman civil servants before reaching other strata (Weber, 1920–1921); it was more palatable to them than the old traditional Roman religion because they perceived it as a symbolic expression of the political philosophy that grounded Roman bureaucracy. Roman civil servants were hierarchized according to grades associated with specific functions; admission into the bureaucracy and promotion from one grade to the next was determined by impersonal procedures. Although the entire system was under the authority of the Emperor, he was regarded as the incarnation of the impersonal rules codified by Roman law. Now, Mithraism was a religion placed under the auspices of a God who too symbolized impersonal rules; as in the case of Freemasonry, so here, believers were admitted and graded according to a scale with the help of impersonal procedures. Weber therefore solved a macroscopic question – why are certain strata more receptive toward a particular religious doctrine? – in an explicitly 'individualistic' fashion, that is, by showing that Roman civil servants had strong reasons for perceiving Mithraism as being more attractive than the old Roman religion, which had originated in the context of a purely agrarian society. In Prussia, Freemasonry appealed more to civil servants than it did to other strata for similar reasons.

The Weberian vein is noticeable in many modern analyses. Merton's classic analysis of the anti-Black attitudes of White American workers during the Great Depression of the 1930s rests on the assumption that White unionists had strong reasons to believe that Black workers, who came from large paternalist farms in the South, were less prepared than White

workers from the South to be loyal to unions (Merton, 1949). Henri Bergeron (1999) wondered why methadone programs adopted in the Netherlands and Switzerland were rejected in France. His answer was that Lacanian theories, highly influential among French psychiatrists, had led them to diagnose drug addiction as the result of the disruption of social relations. French psychiatrists thus concluded that drug addicts could be cured by methodical restoration of their social relations. By contrast, Swiss and Dutch psychiatrists did not believe that there was a theory from which effective remedies against drug addiction could be drawn. As they did not feel capable of curing drug addiction, they believed that their main duty was to protect people, especially against the danger of AIDS, which could be contracted through drug addiction. The French had strong reasons for stressing that their role was to cure; the Dutch and Swiss, on the other hand, firmly believed that their job was to protect since they did not know how to cure. In an analysis such as this, one retrieves the highly flexible theory of rationality used by individualist sociologists who follow the Weberian tradition.

A Particular Version of the Individualistic Tradition: The Rational Choice Model

Contemporary sociology has developed a particular version of the individualistic tradition. Instead of the open, Weberian theory of rationality, it proposes to adopt the theory of rationality developed by economics, according to which social actors are allegedly moved by their interests and are capable of picking out the best means to serve their ends. This model, known as the 'rational choice model,' and first inspired by Jeremy Bentham, is useful. It has led to many constructive theories in several fields, most notably in the sociology of crime, education, and organizations. Its achievements have motivated some sociologists, such as James Coleman, to contend that in sociology it could serve the purpose of a general theory that is able to integrate heterogeneous findings. But this model cannot be deemed a realistic theory of behavior under all circumstances. Mancur Olson (1965) has stressed that his own theory of collective action, which applies the postulates of neoclassical economics, can explain why collective action does not occur as long as its axioms are believed to be realistic. He adds, however, that in many circumstances, it does not occur simply because people are moved and mobilized not only by their interests but also by their beliefs. Now, beliefs can seldom be satisfactorily explained by the interests of social actors alone. All in all, the 'rational choice model' has produced many convincing theories, but it cannot be regarded as a general theory, neither actually nor potentially.

What the styles of research illustrated by these examples hold in common are explanations of social phenomena that follow the criteria generally used in all scientific disciplines. In this sense, they belong to the 'positivist' category of the previous typology.

Interpretation versus Explanation

In his book on the methodology of the social sciences, *Problems of the Philosophy of History*, Simmel (1892) made the important point that history and the social sciences naturally raise two types of questions: one that can and one that cannot be given a unique, scientifically controlled answer. According to Rickert's vocabulary, some questions raised by sociologists aim at 'explaining' while others aim at 'interpreting' social phenomena. In his *Philosophy of Money*, Simmel (1900) himself proposed an *explanatory* theory for the decline of feudalism: from the moment that peasants in the Middle Ages could pay their rents in money rather than in kind, they were able to decide what to grow; placed in a position that allowed them to produce and sell surpluses, they became eager to participate in collective actions against landowners. Thus an apparently minor institutional innovation generated a chain reaction that eroded the feudal organization of society.

Other questions, however, call for '*interpretation*' (or '*description*') rather than 'explanation.' What are the main features of modernity? Will the twenty-first century be characterized by a religious revival? What does it mean to be poor in an affluent society? How do people live in poor areas? Such questions, of course, cannot be answered in one way. There are many ways of describing life conditions in a poor area. In short, thanks to the very nature of such questions, answers to them are doomed to be at least partly subjective. Actually, as Simmel states, questions of this sort can be answered in an interesting fashion only if analysts are able to inject their own sensibility into their description or interpretation. On the whole, answering these questions requires an ability that makes sociologists akin to artists. A good biographer, for instance, cannot simply follow the criteria that define a scientific work. He or she must also be able to give unity to the numerous observations collected from witnesses on the subject of the biography, on that person's behavior and decisions in innumerable circumstances. Many sociological works are faced with the same types of questions. Anthony Giddens's (1984) study of postmodern society, like Burckhardt's earlier study of the *Kultur der Renaissance in Italien* (1952[1860]), is an example of a work that attempts to characterize the main features of a historical era or identify broad historical trends. Other works dealing not with societies as wholes, but rather with local phenomena also belong to the interpretative–descriptive rather than the explanatory category; although they deal with social reality, they evoke the procedures of novelists. Oscar Lewis's *The Children of Sanchez* (1961) is a classic illustration of such 'literary' sociology. The anthropologist Clifford Geertz (1973) coined the expression 'thick description' to characterize the methodology of this type of work, while W.G. Runciman (1983–1997) developed methodological considerations that seem to elaborate on Simmel's insights.

A Complex Identity

In sum, all the types of sociology derived from the combination of these three principal ideal-typical objectives (explaining, informing, criticizing) and the four types generated by the combination of binary variables, 'holism' versus 'individualism' and 'positivism' versus 'hermeneutics' can be illustrated as easily through examples drawn from contemporary as from classical sociology. Perhaps this demonstrates that all these types are legitimate and fruitful. The price of this heterogeneity

lies in the difficulty of pinpointing the identity of sociology, while its benefit lies in sociology's ability to fill the gaps that other social sciences more devoted to a single paradigm, such as economics, are unable to fill.

EDITOR IN CHIEF BIOGRAPHY

James D. Wright received his bachelor's degree in philosophy from Purdue University in 1969, a master's degree in sociology from the University of Wisconsin in 1970, and his PhD in sociology from Wisconsin in 1973. His first academic appointment was at the University of Massachusetts, Amherst, where he was promoted to Associate Professor in 1976 and to Full Professor in 1979. Most of his 15 years at Massachusetts were spent as Director, Associate Director, or Director of Research in the Social and Demographic Institute.

Wright left Massachusetts for Tulane University in New Orleans in 1988 where he served as the Charles and Leo Favrot Professor of Human Relations in Tulane's Department of Sociology. He also enjoyed a courtesy appointment in the Tulane School of Public Health, Department of Biostatistics and Epidemiology. He left Tulane in 2001 to become the Provost's Distinguished Research Professor of Sociology at the University of Central Florida. In 2003, he was named as the Director of the University's Institute for Social and Behavioral Sciences and in 2013, was designated as a UCF Pegasus Professor, the University's highest faculty honor.

Wright was the Editor in Chief of the scholarly journal *Social Science Research* from 1978 until 2014. His previous editing experience also includes a 20-year stint as editor of the Aldine de Gruyter book series *Social Institutions and Social Change*, two editions of the *Handbook of Survey Research* (Academic Press, 1983; Emerald Publishing, 2010), and service on the editorial boards of numerous journals. He is the author of 21 books and scholarly monographs on topics ranging from homelessness to research methods to NASCAR, and he has published more than 300 journal articles, book chapters, reviews, essays, and polemics. Wright lives with his wife Christine Stewart and their multiple dogs and cats in Winter Springs, Florida, where in his spare time he likes to cook fancy meals for large crowds.

PREFACE TO THE FIRST EDITION

Large and ambitious works such as the present Encyclopedia depend on countless instances of input, cooperation, and contextual support. Therefore, the editors in chief would like to express their gratitude to several institutions and individuals. Our most general thanks go to our respective home institutions, the Center for Advanced Study in the Behavioral Sciences, Stanford, and the Max Planck Institute for Human Development, Berlin. We are certain that without the effective infrastructures of these institutions and the rich collegial networks and intellectual climate they provide, implementing this Encyclopedia in such a short amount of time would not have been possible. In this context, we also need to mention that due to the administrative budgets provided to the editors in chief by the publisher, the financial strains on our home institutions were minimal. Such a situation may be a rarity in the modern world of scientific publishing where publishers often press scholars and institutions into taking on larger and larger shares of the publication enterprise.

Aside from the more than 4000 authors, our deepest thanks goes to the editors of the 39 sections, to whom we delegated many decisions at various stages, who were primarily responsible for developing the lists of articles and authors, and who stood as the main gatekeepers of scientific quality for the entries in their sections. As a group, the section editors displayed remarkable energy, intelligence, and tolerance for the inevitable frustrations of tending large numbers of authors over a long period of time. Because of the brevity of the acknowledgment of the main editorial coproducers here, we alert the reader to the list published as part of the front matter and the description of their extensive work we offer in the Introduction. We would also like to mention that one of our highly esteemed section editors, Franz Weinert, died unexpectedly during the last phases of his editorial work. For people who had the pleasure of knowing Franz Weinert, it comes as no surprise that he completed his editorial duties without ever complaining about the difficult health conditions he was facing. He was a gentleman and a distinguished scholar.

The International Advisors also gave wise counsel on several designated occasions, and a number of these scholars represented on the International Advisory Board took more initiative — always helpful — than we had originally asked. The International Advisory Board was particularly helpful in the process of choosing section editors. Some of its members assisted us ably as we attempted to make the Encyclopedia as international as possible and also in dealing with special problems that are part of a large project with close timelines. Thus, we remember a few occasions where members of the International Advisory Board helped us with their substantive and social competence to deal with matters of editorial disagreements. Because of the overall quality, collaborative spirit, and professional responsibility of our section editors, these events were rare indeed, but dealing with them required masterful and accelerated input. We appreciate the collegiality that members of the Board displayed when called upon in these special circumstances.

In addition, and as described in the Introduction, there was a host of esteemed colleagues who gave us advice on numerous questions such as author and editor selection, organizational matters, topics for entries, content and quality of selected articles, substantive and methodological niches to be covered, as well as last-minute author replacements. The number of such individuals is large indeed, and most likely, significantly larger than the list presented below. There were too many short, but nevertheless significant collaborative encounters that we likely did not deposit into our long-term memory or written documentation. We apologize for such oversights.

In this spirit, we appreciate the advice given in the three planning meetings in Stanford, Uppsala, and Dölln/Berlin by the following scholars: Peter Behrens, Burton Clark, Gordon Clark, Lorraine Daston, Meinolf Dierkes, Jean-Emile Gombert, Torsten Husén, Gérard Jorland, Ali Kazancigil, Wolfgang Klein, Gardner Lindzey, Renate

Mayntz, Andrew Pettigrew, Denis Phillips, Marc Richelle, Ursula M. Staudinger, Piotr Sztompka, Eskil Wadensjö, Björn Wittrock, and Robert Zajonc.

We would like to extend special thanks to Laura Stoker, who pinch-hit for Nelson Polsby (section editor for Political Science) who was unable to attend the meeting of section editors in April 1998; and to Linda Woodhead, Senior Lecturer in Religious Studies, Lancaster University, who assisted David Martin with editorial work at all phases for the section on Religious Studies.

We also acknowledge the help of scholars who advised Smelser and Baltes at the stage of pulling together the entry lists, proposing authors, and occasionally reviewing the content and quality of articles submitted.

Smelser thanks: Jeffrey Banks, Peter Bickel, Edgar Borgatta, Charles Camic, Jennifer Chatman, Jean Cohen, Michael Dear, Pierre Ducrey, Eckart Ehlers, Sylvie Faucheux, Steven Guteman, Frank Furstenberg, Helga Haftendorn, Peter Katzenstein, David Laibson, Stephan Lauritzen, Douglas McAdam, Eleanor Maccoby, Phyllis Mack, Cora Marrett, Douglas Massey, Donald Melnick, Harvey Molotch, Lincoln Moses, James Peacock, Trond Petersen, Andrew Pettigrew, Alejandro Portes, Matilda Riley, István Rév, John Roberts, Dorothy Ross, Rob Sampson, Fritz Scharpf, Melvin Seeman, James Short, Fritz Stern, Carol Swain, Ann Swidler, Ken'ichi Tominaga, Charles Tilly, Wolfgang van den Daele, Sidney Verba, Margaret Weir, Thomas Weisner, and Jennifer Wolch.

Baltes is very grateful to: Nancy Andreasen, Gerhard Arminger, André-Jean Arnaud, Jens Asendorpf, Jan Assmann, Margret Baltes (deceased), Jürgen Baumert, Peter Behrens, Manfred Bierwisch, Niels Birbaumer, Peter Bloßfeld, Walter Borman, Robert F. Boruch, Mark Bouton, Michael Bratmann, David Buss, Shelley Chaiken, Lorraine Daston, Juan Delius, Marvin Dunnette, Georg Elwert, Helmut Fend, Hans Fischer, Peter Frensch, Alexandra M. Freund, Dieter Frey, Jochen Frowein, Gerd Gigerenzer, Snait Gissis, Peter Gollwitzer, Ian G. Gotlib, David Gyori, Heinz Häfner, Helga Haftendorn, Giyoo Hatano, Adrienne Héritier, Theo Herrmann, Otfried Höffe, Ludger Honnefelder, Paul Hoyningen-Huene, James Huang, Günther Kaiser, Heidi Keller, Martina Kessel, Gábor Klaniczay, Wolf-Hagen Krauth, Achim Leschinsky, Karen Li, Shu-Chen Li, Ulman Lindenberger, Elizabeth Loftus, Gerd Lüer, Ingrid Lunt, Hans J. Markowitsch, Laura Martignon, Randolf Menzel, Dietmar Mieth, Susan Mineka, Setsuo Miyazawa, John R. Nesselroade, Claus Offe, Vimla Patel, Meinrad Perrez, Rosa Lynn Pinkus, Robert Plomin, Neville Postlethwaite, Thomas Rentsch, István Rév, Peter Roeder, Richard Rorty, Hubert Rottleuthner, Peter Schäfer, Heinz Schuler, Norbert Schwarz, Richard J. Shavelson, Joan E. Sieber, Burton Singer, Wolf Singer, Edward Smith, Hans Spada, Günter Spur, Rolf Steyer, Michael Stolleis, José Juan Toharia, LeRoy B. Walters, Elke U. Weber, Peter Weingart, and Reiner Wimmer.

There was one more group that played a special role in the editorial review (see also Introduction). Baltes was assisted by a team of colleagues who provided expert input to the section editors and to him during final review: Gregor Bachmann, Alexandra M. Freund, Judith Glück, Wolfgang Klein, Olaf Köller, Shu-Chen Li, Ulman Lindenberger, Ursula M. Staudinger, and Christine Windbichler. Their expertise in helping us to ensure quality is gratefully acknowledged.

The day-to-day organizational work of the editors in chief occurred at their respective research centers — the Center for Advanced Study in the Behavioral Sciences and the Max Planck Institute for Human Development in Berlin. Smelser singles out Julie Schumacher, his main assistant in the project, for her organization of the meeting of section editors, and her superb coordination of the flow of correspondence and manuscripts over several years. She remained firm when the rest of us were faltering, and displayed the greatest efficiency, intelligence, and good cheer. Smelser also relied on periodic help from Leslie Lindzey, Kathleen Much, Jane Kolmodin, and Anne Carpinetti. Michelle Williams of the University of California, Berkeley, served as his main editorial assistant for nearly 2 years, going over all entry manuscripts from the standpoint of readability, and carrying a great part of the cross-referencing work; her judgment was always the best, and Smelser is forever indebted to her.

At the Max Planck Institute for Human Development, and aside from Julia Delius (see below), Baltes expresses his deeply felt thanks to the main secretarial staff in his office (Helga Kaiser, Romy Schlüter, Conor Toomey) who during the preparation of this Encyclopedia took on larger shares of responsibilities for other projects and occasionally helped out when the editorial office was overloaded. More directly involved in the day-to-day operation of the Encyclopedia was Penny Motley, who efficiently functioned as project secretary during the planning phase. During the main phases of the project, it was Yvonne Bennett who was responsible for secretarial and organizational matters. She deserves much applause for her superb and efficient help in the day-to-day running of the editorial office, making sure that all manuscripts and proofs were processed quickly, and also for assisting with the organization of various meetings. Not least, Baltes thanks the administrative office of the Max Planck Institute, and there especially Nina Körner and Karin Marschlich, for their competent work in managing the project budget, as well as Sabine Norfolk who handled most of the numerous fax

transmissions with ever present smiles and friendliness. Finally, in the Berlin editorial office, thanks are also due to Susannah Goss for her excellent work in translating individual articles into English.

Individual section editors wish to thank the following scholars who gave them substantive advice in their work: Richard Abel, Itty Abraham, John Ambler, Karen Anderson, Mitchell Ash, Alan Baddeley, Boris Baltes, Manfred Bierwisch, Michael Bittman, Sophie Bowlby, John Carson, Shelly Chaiken, Roger Chartier, François Chazel, Stewart Clegg, Carol Colby, Philip Converse, James Curran, Jerry Davis, Natalie Z. Davis, Peter Dear, Juan Delius, Michael Dennis, Josh DeWind, Sherry Diamond, Elsa Dixler, Georg Elwert, Howard Erlanger, Drew Faust, Malcolm Feeley, Nancy Folbre, Michael Frese, Angela Friederici, Lawrence Friedman, Bryant Garth; Victor Ginsburgh; Marcial Godoy, Frances Goldscheider, Calvin Goldscheider, John H. Goldthorpe, Reginald Golledge, William Graziano, Stephen Gudeman, Mauro Guillen, Doug Guthrie, John Hagan, Eric Hershberg, Steve Heydemann, Stephen Hilgartner, Judith Howard, William Howell, Jill Jaeger, Bob Kagan, Joe Karaganis, Roger E. Kasperson, Ronald Kassimir, Robert W. Kates, Wolfgang Klein, Hans-Dieter Klingemann, Bert Kritzer, Kay Levine, Steven Lukes, Michael Lynch, Akin Mabogunje, Stuart Macaulay, Donald MacKenzie, David Magnusson, Michael McCann, Sally Merry, Peter Meusburger, Sieglinde Modell, John Monahan, Kevin Moore, Gerda Neyer, Hiroyuki Ninomiya, Jodi O'Brien, Eva Oesterberg, Mark Osiel, James L. Peacock, Susan Phillips, Trevor Pinch, Wolfgang Prinz, Sheri Ranis, Harry Reis, Estevao C. de Rezende Martins, Marc Richelle, Leila Rupp, Gigi Santow, Austin Sarat, Simon Schaffer, Linda Scott, Tim Shallice, Seteney Shami, Ronen Shamir, Susan Silbey, Wolf Singer, Sheila Slaughter, Gerhard Strube, Ursula M. Staudinger, J. Stengers, Stephen M. Stigler, Michael Stolleis, Mark Suchman, Denis Szabo, Verta Taylor, Ashley Timmer, David Trubek, Leslie Ungerleider, Don Van Arsdol, Jakob Vogel, Rita Vörg, Judy Wajcman, Mary Wegner, Wlodzimierz Wesolowski, Steve Wheatley, Björn Wittrock, and Vincent Wright (deceased).

Section editors also thanked the following persons for their research assistance: Pamela Anderson, Susan Augir, Anja Berkes, Chantale Bousquet, Aida Bilalbegović, John Clark, Susanne Dengler, Kathrine Derbyshire, Annie Devinant, Casey B.K. Dominguez, Barbara Dorney, Elizabeth Dowling, Tracey L. Dowdeswell, Carolyn Dymond, Debbie Fitch, Susannah Goss, Verhan Henderson, Andrew Hostetler, Gudrun Klein, Heike Kubisch, Angie Lam, Ellen Lee, Valerie Lenhart, Kay Levine, Allison Lynn, Helena Maravilla, Carol B. Marley, Marion Maruschak, Michael McClelland, Rhonda Moats, Birgit Möller, Katja Neumann, Linda Peterson, Justin Powell, Paul Price, Xandra Rarden, Chris Reiter, Deborah Sadowski, Heidi Schulze, Heidi Sestrich, Keith Smith, Judith Thompson, Karen Varilla, Stuart Vizard, Danelle Winship.

It is difficult to single out one person as especially helpful. Despite the risks involved, we would like to highlight one person (see also Introduction). As shown in the front matter, beginning in the second year of the planning phase, Julia Delius served as our scientific editorial assistant. For our internal process of editorial review and management, Julia Delius was the mastermind of editorial coordination. Her work was simply outstanding.

Finally, we express our thanks to several individuals at Elsevier publishers whose work was both essential and helpful to us throughout. Barbara Barrett started the ball rolling for the entire Encyclopedia project, and was a master at negotiating out the fundamental arrangements at the beginning. Geraldine Billingham, as executive editor, also played an important role in the development of the project, as well as carrying the heavy responsibility for ensuring that all the financial and operational aspects of the project were realized. She executed this work with directness, skill, and tact. Angela Greenwell coordinated the editorial process with dexterity, calmness, and good judgment. Three persons were responsible for monitoring the progress of entries from Elsevier's side: Michael Lax for a time at the beginning; Jayne Harrison, who carried an overwhelming load of manuscripts month after month, and Helen Collins, who was responsible for the equally demanding job of shepherding the manuscripts through the entire production process. Ruth Glynn skillfully and imaginatively masterminded the development of the electronic version within Science Direct. We know how much the success of the Encyclopedia has depended on these individuals and their staffs, and our appreciation and admiration is here recorded.

Our expressions of gratitude and respect for the authors, section editors, reviewers, counselors, and editorial team, however, are not meant to distract from our own responsibilities as editors in chief. Let us hasten to add, therefore, that those whom we acknowledge deserve most of the credit but little of the blame for whatever shortcomings remain.

Neil J. Smelser
Paul B. Baltes
Palo Alto and Berlin

INTRODUCTION

Alan Sica's article in this encyclopedia observes, "The urge to systematize and rationalize both common and esoteric knowledge has been strongly and continuously in evidence for at least 2400 years in the West" (Sica, 2015). Sica dates the origins of this urge to Plato's nephew Speusippus, who took up the challenge of Plato's call for an *encyclopedia* (from Greek words meaning 'general education'), and traces the urge though Pliny the Elder, Vincent of Beauvois, Francis Bacon, Denis Diderot, and a great many others. Today, an encyclopedia is simply a self-contained reference work "with two aims: to include up-to-date knowledge about a particular discipline or group of disciplines and to make this knowledge conveniently accessible" (Smelser and Baltes, 2001). Such are the aspirations of the present work.

Histories of the concept of an encyclopedia are widely available and need not occupy us here. Those interested in where the *International Encyclopedia of the Social and Behavioral Sciences* (IESBS) fits into the long history of encyclopedias will do well to consult the Sica article quoted above or the Smelser–Baltes 'Introduction' to the first edition of this work.

This is the second edition (2/e) of the IESBS. Elsewhere, I acknowledge my immense debt to the editors of the first edition, Dr Neil Smelser and Dr Paul Baltes. Without their perspective and template to follow in assembling the second edition, this version would have scarcely been possible. The very thought of an encyclopedia covering *all* the social and behavioral sciences, one that drew on scholars from *all* corners of the globe, is itself so audacious that one would hesitate even to begin without a pretty detailed road map to the terrain.

On the occasion of the publication of Robert E.L. Faris's widely acclaimed *Handbook of Modern Sociology*, Joseph Gittler was moved to ask, "With the plethora of new handbooks, reviews, and compendia in sociology, one wonders whether there is a need for yet another one." That question was posed almost 50 years ago; the ensuing half-century has been marked, as Sica says, by "an avalanche of reference materials the likes of which had never been seen in libraries prior to about 2000." So readers and critics are within their rights to ask: Why a second edition? Why now?

The first edition (1/e) was reviewed in *Contemporary Psychology* as "the largest corpus of knowledge about the social and behavioral sciences in existence" (Park, 2004). According to readily available data sources, IESBS 1/e has been cited nearly 6000 times in subsequent scholarly literature and has an h-index ($h = 24$) that would be the envy of many full professors. Citations are only one measure of impact, of course, and probably not the most important measure for a basic reference work intended more for students and a general audience than for practicing professionals. In addition to the thousands of scholarly citations, items from IESBS 1/e were 'hit' almost two *million* times on Science Direct between online publication in November 2002 and August 2014 — two million instances where IESBS 1/e was likely consulted as a basic reference source, to get quickly up to speed in a new area of research or to provide background for a paper or project, or just to satisfy a reader's curiosity. The first edition, in short, emerged soon after publication as a go-to reference work throughout the social and behavioral sciences. Michael Shanahan referred to the first edition as "the atomic bomb of reference works." It was thus an easy conclusion that the work had sufficient value to keep it alive and current.

In reading selected articles from the first edition, however, I was taken aback by how much and how quickly they had aged. The first articles I looked at were those pertinent to my own areas of research and in nearly every case, there was important recent work that I felt needed to be discussed. With the assistance of colleagues in other areas of the social and behavioral sciences, it became obvious that this was a general problem. To be sure, much of the material in 1/e has enduring value; indeed, roughly half the articles in 2/e are updated and revised items from the first edition. Still, it is sobering to realize just how quickly the frontiers of social science

knowledge shift and thus how quickly a basic reference source becomes dated. I am certain there are articles in the current edition that are already in need of some updating.

Smelser and Baltes enumerated six criteria that guided their decisions about what to include and what to leave out. The criteria are as follows:

1. secure knowledge, realizing that security of knowledge is a dynamic and relative term,
2. knowledge with balance and comprehensiveness,
3. knowledge that is integrative rather than fragmented,
4. knowledge that places the evidence into historical and theoretical context,
5. knowledge that highlights connections between topics and fields, and
6. knowledge that combines, where possible, theory and practice.

I would like to say I have followed these same criteria in determining the content of 2/e, but all six criteria have proved problematic in one or another way and thus deserve some comment in light of the present work:

1. What is secure knowledge today is apt to be recognized as wrong tomorrow. Many of our requests for updates to 1/e articles generated some response to the effect, "All of this is completely obsolete. We need to write a new entry from scratch." One would expect this to be true of areas of research such as behavioral genetics, say, or cognitive neuroscience or other fast-moving scientific fields, but it also turns out to be true of archaeology, history, and philosophy. The leading edge of research in *every* discipline threatens received wisdom; those who content themselves with received wisdom ('secure knowledge') will quickly find themselves behind the times. So our charge to authors was to focus less on the 'secure knowledge' in their respective fields and more on the cutting edge — the new perspectives, methods, findings, and issues that will animate social and behavioral science research in the coming decade.
2. Throughout the social sciences, the distinction between theory and ideology is sometimes difficult to discern, and so too the distinction between applied research and community or political activism. We need not invoke Max Weber's conclusions about the impossibility of a truly value-free social science to understand that ideological undertones and political preferences can often be detected in social science research work; sometimes, they are quite explicit. Nor is it much of a surprise to learn that many social scientists struggle, not always successfully, to distinguish between what they want the world to be and what the world in fact is. Such struggles are part of the process by which knowledge develops and are thus in evidence in many of the 2/e articles. It would be unwise to enforce by editorial fiat a consensus on issues that the social sciences themselves have yet to resolve.
3. The fragmentation of knowledge *across* disciplines is far more serious that the fragmentation of knowledge *within* them, although the latter is a problem as well. Many well-informed sociologists, for example, take pride in reading widely and can speak with some authority about what is going on in the field, even in areas of sociology that do not directly concern them. I assume this is also true of the other social and behavioral science disciplines and areas. But rare is the sociologist who is cognizant of work being done, say, in social geography *even when*, as is often the case, the fundamental problems, theoretical issues, and methodological approaches are similar. This is a widespread problem across the disciplines: The evolutionary psychologists do not know as much as they should about what the anthropologists are doing; the economists ignore a lot of pertinent work in sociology and political science; etc. For better or worse, disciplinary differentiation is an inherent element in the process of knowledge development and discovery, so this is a reality to be faced, not a problem to be solved. We dealt with this reality mainly in two ways: (1) Authors were encouraged wherever possible to think across rather than strictly within their disciplines. (2) Calling relevant work done in other disciplines to the reader's attention was a guiding principle for the choice of cross-references for each article.
4. Social-constructionist theories of knowledge would argue that knowledge does not become knowledge until it is placed in historical, cultural, social, political, and theoretical context. As put very simply and succinctly in the opening line of the famous text by Berger and Luckmann, "reality is socially constructed" (1966: 1). This is no less true of social science knowledge than knowledge in any other realm. Unfortunately, a great deal of what we think of as social science knowledge is based on biased samples of WEIRD people — that is, Western, Educated, Industrialized, Rich, and Democratic (Henrich et al., 2010). (The same point has, of course, been made by many others.) The WEIRD, thus defined, represent a rather exotic minority group judged by world standards, and the challenge for IESBS 2/e was therefore twofold: (1) to recruit non-WEIRD editors and authors where possible; and (2) to persuade all authors to incorporate comparative, cross-cultural, and

international themes and perspectives wherever it was possible to do so. This effort was more effective in some sections than in others. Moving away from nation-specific literature, themes, and results to a truly *international* (the I in IESBS) account of the social and behavioral sciences was an ever-present *desideratum* in my discussions with editors and authors.

Alas, an emphasis on cross-culturalism often brings to light that everything, or nearly everything, seems to vary by culture, subgroup, ethnicity or nation, and at that point the question arises whether social science generalization is even possible. Are there universals that cross all social groupings? Or does social science dissolve into a mist of group-specific particularities that adduce no general principles? That hardly seems desirable. Yet myopic and ethnocentric fixations on one's own society or culture are scarcely to be encouraged either.

The worst offenders in this regard tend to be social scientists from the USA (and from the West more generally), who, of course, also comprise the largest share of editors and authors for IESBS 2/e. True, as with greenhouse gases, the USA (and the West) also produce the largest share of the world's science, social and otherwise, and so it is inevitable that they also represent the largest share of IESBS 2/e contributors. The Swedish social anthropologist Ulf Hannerz wrote about this very issue in his marvelous essay, "Editing Anthropology" (Hannerz, 2010). Hannerz quotes a Canadian anthropologist who said of the "neighborly presence" of US anthropology that it was like being "in bed with the elephant." The same is true of most or all of the disciplines covered in this work. But then in a passage remarkable for both its insight and its generosity, Hannerz remarks, "No doubt tensions and conflicts may arise out of this situation, but perhaps it is better to understand that the elephant cannot help being an elephant, and that it makes sense for it, in its habitat, to behave in elephantine ways. A well-trained elephant, too, can do a lot of good, such as in carrying heavy loads." So if the elephant that is Western social and behavioral science has been pressed to carry the heavier load in these pages, that is, the price to be paid for being an elephant in the first place.

The larger issue here is that the social and behavioral sciences, which were largely birthed in the West, in Europe and the United States, mainly address a trans-Atlantic scientific dialogue, a dialogue that is carried out almost exclusively in English. Indeed, throughout much of the world, a scientist's stature is indexed in part by his or her success in publishing in English. Publications in the native language are simply *assumed* to be inferior. The main exceptions, tellingly, are French and German social scientists whose native-language publications are valorized. A Dutch or Portuguese or Hungarian social scientist who only published in the native language would be seriously punished in merit and tenure reviews. Elsevier's citation database Scopus *requires* English-language abstracts before a journal will even be considered for inclusion. And English (with American spellings) is likewise the official language of this encyclopedia. No resources were made available to get articles submitted in other languages translated (although several such articles were submitted). Inevitably, this biases the encyclopedia's coverage in favor of social science addressed to the trans-Atlantic dialogue. Consequently, a great deal of excellent social science published in Spanish, or Mandarin, or Farsi, or any of the other world languages, is overlooked.

That said, steps were taken to improve the internationalism of the encyclopedia's coverage throughout the 4 years of its development. To begin, I sought area and section editors from around the globe and urged them whenever possible to seek international (vs strictly Western) authors. Articles were often returned to their authors with explicit instructions to add international coverage. And when all efforts failed and we ended up with articles that were unmistakably restricted to a single nation in their coverage (frequently but not always, this was the US), I indicated the national focus in the article subtitle. Still, a great deal more WEIRD social and behavioral science remains in these pages than would be desirable in an *international* encyclopedia. In a later section, I give the national breakdown of everyone involved in this project.

5. An encyclopedia that "highlights connections between topics and fields" is easier to envision than to accomplish. Criterion (3) above speaks to the disciplinary fragmentation of our social science knowledge. William Easterly, the NYU economist, has written about the 'tyranny of experts' but the tyranny of the disciplines is an equal problem, a tyranny sanctified by the very academic structure of the modern university, where the separate and often warring colleges are each comprised of assorted departments, the latter representing basic academic disciplines. Interdisciplinary programs are almost invariably relegated to various centers, institutes, or specialized research laboratories — in short, to the periphery of the university's power structure. And while everyone *says* they want to encourage multi- and interdisciplinarity, very little is done to make that happen. Instead, departments remain as the fundamental unit of academic organization.

   Hortatory admonitions to editors and authors have made IESBS 2/e somewhat more interdisciplinary than its several predecessors, but in the end, the disciplinary emphasis in many of our articles would be hard

to overlook. Still, there are many sections of the work that were clearly developed with interdisciplinarity in mind and in which one finds interdisciplinary social science at its current best: environmental and ecological sciences; health; life course; sexuality; GLBT studies; public policy; evolutionary sciences; war, peace, violence, and conflict; and genetics, behavior, history, and society are a few sections that come immediately to mind.

I am particularly pleased with the extensive coverage given in 2/e to the interactions between the biological and social sciences. Harry Whitaker once remarked in a private e-mail that "we are all witnesses to the marriage of biology and the social sciences." Many of the articles found here are offspring of that marriage. And those articles leave little doubt that the future offspring of this marriage will be among the most exciting and insightful social science products of the coming decade.

The social sciences once resisted everything biological as rank reductionism; in addition, the social scientists have always feared that a mature and complete biology would eventually drive us out of business. Articles included in IESBS 2/e make it clear that 'nature' versus 'nurture' was the wrong question from the very beginning, that what we need to understand is how biological inheritance and social and cultural forces *interact* to produce individual and collective outcomes. This is where a lot of the interesting action in the social sciences is going to be in the coming years.

6. The coverage of the practical or applied sides of the various disciplines has been increased in this edition, so the applied content of 2/e certainly exceeds that of its predecessor. New to this edition is the entire section on applied social and behavioral sciences; also new is our large section on social work and the separate section on applied, industrial and organizational psychology. But as Sara Strickhouser and I say in our article on the history of applied social research, "The history of 'applied social science' is indeed the history of the social sciences themselves" (Strickhouser and Wright, 2015). All of the social sciences in their modern form were birthed in the post-Enlightenment effort to understand why people, their institutions and society as a whole were as they were — why greed was more visible than generosity, why oppression was more common than freedom, why inequalities of various sorts characterized every social institution. To the founders of the disciplines, the modern distinction between basic and applied scientific concerns would have seemed meaningless, as indeed it was.

The Planning Phase and Editorial Structure

Elsevier's original acquisitions editor for this project, Scott Bentley, discussed the broad outlines of our attack on IESBS 2/e with me in a series of phone calls in the early months of 2010. By May 2010, certain of these outlines had come into sharp relief. There would be a single editor in chief with a tier of 'responsible lieutenants' to assist. These lieutenants started out as advisory editors but soon morphed into the 10 area editors in the final editorial structure. Each area editor would in turn oversee various sections and each section would have its own editor or editors. The original plan was that the area editors would each be responsible for approximately 400 articles and each section editor responsible for about 100 articles, so that no one would have an excessive amount of work compared to everyone else. In the end, however, some sections required more articles and others fewer, so the areas vary from fewer than 300 to more than 600 articles, and the sections vary from fewer than 30 articles to well more than 200.

Prior to my first discussions with Scott Bentley, Elsevier had commissioned about 20 'market surveys,' roughly half from professional librarians and the other half from academics, each focused on 'what was right and what was wrong' with the first edition. The most insistent demand that surfaced was for a fully electronic, computer-searchable work either in addition to or instead of a print version. In the end, both an e-version and a print version are being made available. But there were also consistent concerns expressed about spotty coverage of some areas: no coverage of social work to speak of; inadequate coverage of accounting, marketing, and business; no separate section of criminology; haphazard coverage of applied topics and concerns; and so on. And there were the predictable concerns about undue Western domination of the work.

Working from the 1/e Table of Contents and this stack of 20 surveys, I tinkered for a few months with how best to expand coverage to address the concerns our reviewers had expressed; the result was (more or less) the editorial structure shown elsewhere in the front matter of this work. Thus, the 53 sections of 2/e are basically the 39 sections of the first edition plus sections that were added to cover important emerging areas of research interest (e.g., gay, lesbian, bisexual, and transsexual studies) or to provide deeper coverage of disciplines and subdisciplines that the first edition treated lightly if at all (applied social and behavioral sciences, social work). A

few of the first edition sections were eliminated entirely: specifically, integrative concepts and issues (something of a catch-all category for 1/e articles that were highly interdisciplinary or simply did not fit anywhere else) and gender studies (gender is now so thoroughly integrated into the research and thinking of all the social and behavioral science disciplines and subdisciplines that a separate section was unnecessary and somewhat retrograde). Others were altered or expanded in significant ways (organizational and management studies, for example, became the second edition section on management, organizations, business, marketing and finance; expressive forms evolved into the 2/e section on culture and the arts; linguistics was subdivided into three separate sections; etc.) And some subdisciplinary areas that were part of other sections in the first edition were given their own sections in the second (life course studies; sexuality; criminology; labor studies; and war, peace, violence, and conflict are the most prominent examples), just to ensure adequate coverage.

The Introduction to 1/e (Smelser and Baltes, 2001) discusses at great length the intellectual architecture of the first edition and its evolution; the agonizing decisions about rules for the biographical articles; whether to organize the work by discipline, by concept, by an a priori taxonomy of social science knowledge, or in some other manner; and related structural matters. What resulted in 1/e was something of a hybrid model with some sections clearly representing specific disciplines, others representing 'overarching topics,' still others representing 'intersecting fields,' and so on. My task was far less challenging: I thought the architecture of the first edition served its purposes admirably and so I adopted it wholesale for the second edition, with the small modifications noted above.

While each of the 53 sections of 2/e has some more or less obvious justifying logic or substantive or disciplinary coherence, their arrangement into the 10 areas of the second edition does not. As already indicated, decisions about what sections to include and exclude were made very early in the development of the second edition, based on what was in the first edition, what Elsevier's marketing surveys suggested as significant lacunae, and my own sense of things. The arrangement of the sections into areas came later and was dictated largely by the interests and expertise of those who had been persuaded to sign onto the enterprise. Thus, all the Linguistics sections are in Area Five along with the cognitive and neuroscience sections because Harry Whitaker at Northern Michigan University had been a linguist first, a neuroscientist second, and a historian of psychology third. Likewise, Area Eight contains its seemingly chaotic hodgepodge of evolutionary sciences, genetics, religious studies, science and technology studies, and law because these happen to be the fields of interest of the redoubtable Barbara Prainsack of King's College, London, whose editorial talents are as deep as her interests are broad. Simplifying only slightly, section editors were chosen for their substantive expertise in particular areas of research (as well as their international or cultural 'range'); the plan was that section editors would review each of their articles for completeness of coverage, currency, fairness, and the like. In contrast, area editors were chosen for their breadth of interest and knowledge spanning multiple sections – people who by nature, experience, and training would be good at seeing the big picture. The role of the area editors was to assure that the articles were at least modestly international and interdisciplinary and formed some sort of coherent whole.

As laid out in an early e-mail to one of the area editors, "In my mind, Advisory [Area] Editors are generalists and Section Editors are content specialists. The Section Editors need to bring breadth of knowledge to their responsibilities, of course, but the primary job requirement is expert understanding of the particular field or section. We need section editors who can commission pieces that adequately review past developments in the subject area, but who can also shape their portfolios to identify major unanswered questions and new research developments." This was the general model followed throughout the recruitment process.

The approach just sketched inevitably left a residual area made of up sections that none of the other area editors were willing or able to claim. That proved to be Area Ten. A very large number of scholars from various disciplines and world regions were approached about serving as the Area Ten Editor. All demurred until I approached Martin Bulmer of the University of Surrey, who served the project for about a year but was unable to continue and subsequently left the Board. So for the final year of the project, the editing of Area Ten was done mainly by me.

The online subject classification for IESBS 1/e did not correspond precisely to the sections of the first edition; the subject classifications listed articles by broad general topic regardless of which 1/e section developed them. So for the first year or so, my assistants and I labored to assign every 1/e topic to one of the 53 2/e sections. With 53 sections to populate with articles and about 4000 articles to classify, the process of assigning articles to unique sections occupied huge amounts of time and generated endlessly complicated spreadsheets. (After about a year of this, a document surfaced in the Elsevier archives that showed exactly where each 1/e article had originated.)

Along with populating the 2/e sections with articles, searching for area and section editors occupied a major part of the early going. The original idea was to identify the 10 area editors first and then enlist them in the

search for their section editors, but in fact, these processes were simultaneous and were about half-completed when the two planning meetings were held: the first in San Diego on 19 and 20 May 2011; the second in London on 5–7 June 2011. Although not part of the plan, the first meeting was mostly attended by area editors and the second, by section editors.

The agenda for both meetings was largely identical: achieve clarity on the respective roles of the various editors; solicit advice on filling the unfilled editorial slots; get buy-in on the project *mantra* (internationalism, interdisciplinarity, inclusiveness!); explain the relationship between the first and second editions (e.g., that all 1/e authors would be offered the opportunity to update their articles); explain the process of assigning articles to sections; and the like. In almost all cases, consensus was quickly forthcoming.

The largest substantive change in the second edition is the treatment of psychology. (Whether measured by students, practitioners, professors or programs, psychology is the largest of the social and behavioral sciences.) In the first edition, the whole of psychology was contained within four large sections: clinical and applied psychology; developmental, social, personality, and motivational psychology; cognitive psychology and cognitive science; and behavioral and cognitive neuroscience. Cognitive science and neuroscience are, of course, rapidly growing sectors of the psychological discipline and it seemed appropriate to devote an entire area of the second edition to them. This area contained seven separate sections (three of them devoted to linguistics). And the 'softer' psychological sciences were placed in a separate area comprised of eight sections (including psychiatry and social work). These changes were made to assure that 2/e had adequate coverage of the entire psychological enterprise (a concern that was raised in some of the reviews of 1/e).

The structure of the editorial team was developed to serve two purposes: first, to divide up the labor into manageable parts; and secondly, to assure that every article in the final product would be reviewed by at least three scholars: the respective section editor, area editor, and the editor in chief. Since we were all aware of one another's identities throughout, the review process was not blinded, but every article in this work has been thoroughly peer-reviewed and vetted. In many cases, these articles have been through four, five, six, or even more revisions before being accepted for inclusion in the work.

Recruiting Editors and Authors

IESBS 2/e faced two different recruiting tasks: recruiting editors and recruiting authors. As indicated elsewhere, the original plan was that I would recruit area editors largely from my own personal networks and they in turn would recruit their section editors. In practice, the process was much more convoluted. First off, many of my 'first choice' candidates were hesitant to involve themselves in such a daunting and ambitious project. In some cases, an initial agreement to come aboard was followed a few weeks or months later by withdrawal as the true scope of work came into sharper focus. Some people that I tried to recruit as area editors demurred but agreed to serve as section editors; in other cases, candidates for area editors were nominated by section editors. In a couple of cases, there was a complete team of section editors prior to the successful recruitment of a corresponding area editor. And so on. The process of assembling an editorial team for the project was by no means linear.

Personal networks – mine and those of the people I persuaded to sign on – were the largest single source of ideas for other editors, by far. But personal networks tend to follow disciplinary and national lines and become rather quickly exhausted. In selecting both editors and authors, it was of course essential that all relevant perspectives be covered and that the breadth of fields was adequately represented. So other sources of ideas were tapped: the expertise of the Major Reference Works team at Elsevier; editorial boards of leading journals in the respective fields; Google Scholar citation counts; the knowledge and networks of people who had been involved in preparing the first edition – basically, anywhere names of top scholars in particular areas could be located. I did not keep systematic track of the number of people approached, much less of the outcomes; but in reviewing my e-mail archives from the early period of the project, I probably asked (on average) somewhere between six and eight prospects before I found someone to agree (an average that was highly variable across the areas and sections).

In the initial plan, area editors would recruit their own section editors and the section editors would in turn recruit their own authors, but the reality was again different. Inevitably, my negotiations with prospective editors (both types) would often result in a declination of the editorial role but an offer to write an article on a particular topic (or topics), offers I readily accepted. So in some cases, I had committed authors of particular articles well before I had the corresponding section or area editor in place. And many of the section editors likewise leaned on their area editors and on me for author suggestions, contacts, and outreach. So all the editors

were involved in locating willing authors (and not coincidentally, in making suggestions for articles to be included in the final work).

No one was asked to keep precise statistics on how many authors were sought before an agreeable author was found. My sense is that the 2/e editors had a somewhat tougher time with this than the 1/e editors had (but on the other hand, the 2/e editors had all the 1/e authors to work with, which Smelser and Baltes certainly did not have). The 1/e editors report that about 60% of those invited to write articles agreed to do so on the first 'ask' (with equivalent success rates in each subsequent 'ask'). In 2/e (or so I would guess), the success rate was probably closer to 50% and possibly even lower. They also report that something in excess of 90% of those who agreed to write for 1/e in fact contributed "acceptable entries in time to be included…" In the 2/e case, we found ourselves still soliciting authors within a few weeks of the submission deadline and some dozens of authors pulled out of the project at the last minute. Still, when all the dust settled, there were just about 800 articles planned for both editions that never materialized and both editions ended up with just fewer than 4000 articles. Perhaps these are 'natural limits' for a work of this sort.

Biographies*

In the Introduction to 1/e, Smelser and Baltes provided a short history of and rationale for the decision to include a limited number of biographical articles (150 of them, to be exact). This was evidently a controversial and contested decision since some of those associated with 1/e felt that biographical articles had no place in an encyclopedia focused on substantive knowledge (versus the personalities of those who produced it). As Newton said (paraphrasing a passage from Bernard of Chartres), "If I have seen further, it is by standing on the shoulders of giants" (a passage made famous among social scientists by Robert K. Merton's *On the Shoulders of Giants* (1965)). In other words, discovery is only possible because its discoverer is able to refer to knowledge already gathered and accumulated by his or her predecessors; and since all discoveries – small and large, substantial and minor – contribute to the production and accumulation of knowledge, singling out particular scholars for special attention would be both pointless and invidious.

This position, although understandable, was abandoned in the first edition and remains so in the second, largely because it is not possible to understand the social sciences without knowing the individuals who contributed to it. C. Wright Mills once defined the sociological imagination as the intersection of biography and history (Mills, 1959). To know the social sciences therefore requires biographical and historical knowledge. The social sciences are distinguished from the physical and biological sciences in the way they produce knowledge because individual human beings, including social scientists, invest meaning in their actions. Only through understanding the meaning that individuals give to their actions are social scientists able to provide explanations of human behavior and its outcomes. And what applies to social action in general applies to the production of social science knowledge as well. It thus makes sense to include biographical accounts of social science personages who have been particularly distinguished in making sense of human action and have in turn made major contributions to social science knowledge. To acknowledge individual social scientists with biographical articles is also to acknowledge their special and particular insights.

Once the decision was made to include biographies in 1/e, the next major decision was whom to include and whom to leave out. Two arbitrary but defensible principles governed these decisions: (1) the total number of biographies was not to exceed 150 (chosen because it seemed like a manageable number) and (2) only biographies of the dead would be included. The 1/e section editor for biographies, Karl Ulrich Mayer, consulted handbooks and encyclopedias, asked other section editors to name and rank the most important names in their respective disciplines, ran citation checks, and finally submitted a consolidated list to various experts for review. This resulted in some additions and some deletions and in the end 147 biographies made it into the first edition.

Instructions to authors writing these biographies directed them to include "a brief sketch of the major dates and events in the life of the biographee," to describe "the major contours of the [person's] substantive contribution," and to highlight the "importance and relevance of the biographee's work for the social and behavioral sciences." Largely the same instructions were given to 2/e biographers.

The selection criteria for 2/e were very different. First, on the reasoning that well-done biographies of leading figures is one of the things that draw readers to a work such as this, the total number of biographies was

* My thanks to Andreas Hess for drafting this section of the Introduction.

increased by more than 100 (to just over 250). In a major departure from 1/e, much of the increase is made up of biographies of the living. The 1/e restriction that excluded living persons resulted in anomalies that we thought needed to be addressed. As life expectancy has expanded in the twentieth and twenty-first centuries, so have the life spans of social scientists. Claude Levi-Strauss, to cite one obvious example, lived to the age of 101 years. When 1/e was published, he was in his 90s, was widely cited, was recognized universally as a modern classic, indeed a genius, of social anthropology – and yet, owing simply to his longevity, he was not included in the 1/e biographies. Biographies of, for example, the economist Herbert Simon, the political economist Albert O. Hirschman, the sociologist and philosopher Jürgen Habermas, and the linguist Noam Chomsky were all excluded for the same reason; indeed, Habermas and Chomsky still live as this is being written (Fall, 2014). In all these cases, the major works had been produced decades earlier, their major imprints on the social and behavioral sciences were already evident, their eventual inclusion in works such as this was inevitable. Are readers to be deprived of accounts of their lives, times, and contributions just because they have survived into deep old age?

Once the decision was made to include biographies of the living, however, it was not always easy to decide who among the living merited inclusion. Often the editors had to make decisions on a case-by-case basis, frequently in extended consultation with colleagues or experts in the field. Criteria used to make these decisions were whether the potential biographee had a reputation beyond one culture, nation, or language group; whether there was a record of sustained production over several decades; and whether there was an impact beyond the confines of a single discipline. These criteria reduced our list of suggested biographees considerably. Early lists of candidates numbered as many as 200 new names (in addition to the 147 biographies included in 1/e). In the end, as noted earlier, somewhat more than 100 new names were added.

In a few cases, persons were included that arguably did not satisfy our inclusion criteria. One such is Raul Hilberg, who became famous mainly for having written one very important book, *The Destruction of the European Jews* (1961). Hilberg's book is still regarded as the seminal work in Holocaust studies, a field of research that came to prominence much later; we felt that his signal contributions to Holocaust studies merited a biographical article. Much the same could be said, perhaps, of André Gorz, a well-known social theorist from France, and Albert Memmi, whose work is on colonialism, anticolonialism, and racism. These and other examples could and probably will raise questions about the porousness of our criteria. Whether we were right in giving 'trespassers' their space is open to debate. In any case, whether Hilberg, Gorz, Memmi, and others do or do not merit their biographies is for readers, not us, to decide.

Other important changes in the 2/e biographies section include, first, a conscious effort to attain a better gender balance, including more women both as biographees and as authors; and second, expanding the biographies both geographically and culturally. In the end we made some inroads in both respects but fell short of our internal goals. One of the main reasons for this is that any encyclopedia must, in the first instance, be true to the disciplines it represents. This means being true to the real status of important players, their networks and disciplinary power relations, and their academic capital in their respective fields and beyond. Change in these respects has been noticeable; certainly, the growth of the social sciences in Asia has been remarkable; and in most disciplines, the proportional presence of women has increased. But modest change in the right direction does not a revolution make. Too many nonwhite, non-Western, and nonmale practitioners are still being left out on the disciplinary peripheries and are not fully represented – not in their home disciplines and not in our encyclopedia either.

We state this fact with regret. In many cases, the limiting factor is not excellence but simple visibility. Being part of the trans-Atlantic social science dialogue and engaging this dialog mainly in English translates into more visibility, as discussed earlier. This gets a scholar on the radar screen. Equally excellent work engaging other intellectual dialogues in languages other than English does not. A great many outstanding scholars have thus gone unrecognized in 2/e for precisely this reason. That being said, strenuous efforts were made to make the 2/e biographies more inclusive. Among those included are the Argentinean educationalist Sarmiento, the Brazilian sociologist Cardoso, and the Japanese political scientist Maruyama, to name just a few. This is, however, 'just a few' of the many dozens of prominent social and behavioral scientists 'out there' whom we would have included had we been given more time and more resources (to get non-English works translated, for example). We do feel that we have made some important inroads and beg the reader's understanding of the limits within which we worked. We can only hope that the next edition will strive for more inclusiveness and better representation than we were able to achieve.

Another entirely new feature in the 2/e biographies is the series of 'collective biographies.' In many instances, the intellectual lives of individuals who work in research groups intersect and form a network that makes the

entire group (or paradigm) successful. Examples include articles on the Durkheimians, the Annales School, the Frankfurt School, and several others.

As indicated earlier, instructions to authors were changed little from 1/e. All authors were asked (1) to include the most important biographical facts (country of origin, generation, education, influences, other formative experiences, networks, etc.); (2) to list the most important output (discoveries, publications, etc.) and to briefly discuss the subject matter and content of the most important publications or discoveries; (3) to look at the lasting impact of the person and his or her work (if possible, beyond just one discipline, language group, or culture); and (4) to provide a bibliography of primary and secondary sources related to the biographee and his or her work. Most authors stuck to these guidelines.

Finally, we state for the record that there are a number of important social and behavioral scientists that we would have liked to include but for whom we were unable to find a proper biographer. The search for biographers went on for nearly 4 years. In many cases, our first-choice author agreed at once, but in other cases, we approached four, five, or even more people before an agreeable author was found. And in about two dozen cases, no such author was ever found, with the result that a deserving person's biography had to be dropped. Forgoing a case-by-case discussion of these deletions, let it be simply noted that this is why we have not included biographies of people such as Amartya Sen, the economist and social philosopher; Raymond Boudon, the French sociologist; Ronald Dworkin, the legal theorist; Avishai Margalit, the philosopher; or a collective article for the British Marxist historians (Eric Hobsbawm, E.P. Thompson, Christopher Hill, and Perry Anderson). Perhaps our most regrettable omission is Neil Smelser himself, for whom no biographer could be found despite at least a dozen attempts. (Paul Baltes's biography is included.) Neil is one of the giants on whose shoulders we all stand.

Redundancy

I mentioned earlier that in the beginning of the project, there was no 'map' linking each of the 1/e articles to its respective 1/e Section. Our efforts to create such a map invariably bogged down every time we hit an article that could plausibly belong to any of several sections, which was often. Obviously, it would have been possible to force every article into a 2/e section, but at the time it seemed advisable to involve the editors themselves in these decisions. So on numerous occasions, I distributed lists of 'orphaned' articles (articles for which no home had yet been designated) to the area and section editors, asking for foster parents to volunteer. Eventually, of course, every article found a home, but at a relatively late date in the process, I became aware that a few dozen articles had found more than one home. That is, some of the editors adopted articles without filing the appropriate paperwork with the editor in chief! In such cases, the result was two articles on the 'same' topic. (The 2/e Table of Contents was scoured multiple times looking for precisely these kinds of duplications but in the end, several proved elusive.)

In the large majority of cases, the content of the 'duplicate' articles was sufficiently distinct that both articles were retained, often with some retitling to help readers differentiate between them. For example, readers will find two articles on 'social identity.' One was recruited for the section on social psychology; the other for the sociology section. With rare exception, the two articles discuss different aspects of social identity from entirely different disciplinary angles; indeed, the two articles share only a small handful of common references. So it was an easy decision to retain them both: one appears here as Social Identity in Social Psychology; the other as Social Identity in Sociology. Careful readers will find perhaps a score of similar cases in the encyclopedia.

Alas, in a few regrettable cases, the overlap between duplicate articles was so pronounced that one of the articles had to be deleted. Since by the time these problems surfaced the articles had (often) been written and rewritten several times and had been accepted by both the section and area editors, the last-minute decision to delete a redundant article was painful. My sincere apologies to the authors involved.

Some redundancy in a work of this scope and aspiration is not only inevitable, it is probably also desirable. A reader interested in, say, social inequality will (one hopes) want to know what the sociologists, anthropologists, economists, and geographers all have to say about that topic. And if a few of the many articles on the topic say more or less the same thing, then what harm is done? Editors at all levels were asked to be alert to redundancies across articles and the editorial record shows that many were. That being said, quite a bit of topical redundancy no doubt remains, and that is not (in general) a matter of concern. It is what Smelser and Baltes refer to as the "inevitable residue of overlapping."

The Review Process

Once the table of contents had stabilized, each of the editors was asked to review the 1/e articles assigned to their section or area and come to various decisions. In some cases, 1/e articles could be reprinted more or less 'as is,' with perhaps some updating of references for readers seeking entry points into the current literature. This was especially the case with what were eventually designated as 'legacy articles,' e.g., Gabriel Almond's article on Civic Culture, James Gregor's article on Dictatorship, &c. In other cases, the 1/e articles needed some updating to be suitable for 2/e, either by their original authors when available or by others recruited specifically for the purpose. The general rule was that all 1/e authors would be offered the opportunity to do the updates themselves, and that other authors would be sought in the event of the original authors' declinations. In still other cases, the 1/e article was so obsolete than an entirely new article would be required. And then finally, the review of 1/e articles often revealed areas of current research that were inadequately covered; in these cases too, completely new articles would be sought.

Where appropriate, the relationship between the 1/e and 2/e versions of an article is spelled out in the article tagline. In many cases, there were issues of authorship to resolve — a 1/e article written by *X* and completely revised by *Y* is *Y*'s article although *X* might be identified in the tagline; but what of an article written by *X*, now deceased, and only modestly revised and updated by *Y*? Every decision rule that I formulated to resolve such issues soon confronted an exceptional case where the rule did not seem to apply. So in the end, the only workable rule was that everyone should get proper credit for their intellectual property, whether prime author or reviser, whether living or dead. If exceptions to this rule have crept into the final product (as they almost certainly have), I offer my apologies to those whose work has been slighted or improperly recognized. Deciding on proper authorship for many of our articles was a far more involved and difficult task than expected.

The section editors formed the first line of editorial defense and were the ones to whom article drafts were originally submitted. The section editors read and commented upon the draft articles and returned them to authors for revision. It is a rare article that appears here in its original form: on average, articles were revised two or three times before being sent to the area editors and subsequently on to me; in many cases, it was more like five or six revisions, with subsequent revisions at the request of the area editors and the editor in chief. And in some cases, articles were submitted to outside readers for independent review. As I stated earlier, the reviewing process was not blind, but it was quite thorough, as is reflected in the exceptional quality of the final product.

Internationalism and Inclusivity

A truly *International* Encyclopedia of the Social and Behavioral Sciences would of course require a global network of editors and authors *and* a commitment to internationalize the content of the work wherever possible. With respect to the editorial team for 2/e, this was definitely realized. The section editors and editors in chief who produced the first edition were drawn from only nine countries: The United States, Germany, Italy, Canada, Sweden, Australia, France, Switzerland, and the UK. Two-thirds of those editors were from the USA and only 13% were women. Area and section editors for 2/e represent 21 countries, US scholars make up only 38% of the total, and women comprise 36%. Thus, the proportional representation of women among the editors was nearly tripled in 2/e over 1/e while the predominance of the USA was halved. Nations represented among the editors of 2/e that were not represented in 1/e include Luxembourg, Greece, Finland, Japan, China, Ireland, Singapore, Spain, Russia, Austria, Israel, and the Netherlands. The presence of several Asian nations on this list is particularly gratifying. To be sure, the North Americans and Western Europeans still predominate, but they no longer monopolize the field.

Adding the International Board of Consulting Editors (see the following statement of Acknowledgments) increases the internationalism of the editorial team even further. Of the 45 members of that Board, only 12 (27%) are US social and behavioral scientists. Countries represented on that Board that are not otherwise part of the editorial team include three Central and South American nations (Venezuela, Argentina, Costa Rica), several Asian nations (the Philippines, Malaysia, South Korea, India), a few Western European nations (Norway, Denmark), two representatives from Central and Eastern Europe (Hungary, Croatia), two from the Middle East (Lebanon, Qatar), and one from South Africa. These editions bring to 35 the total number of countries with representation on the IESBS editorial team.

Much the same can be said of the 2/e authors, who are also more international than the 1/e authors had been. Smelser and Baltes noted in their Introduction that while authors from 51 nations were represented in the work,

58% of the authors were from North America and another 35% were from (mainly Western) Europe. "As to gender composition, 21% of the [1/e] authors were women." In 2/e, the proportion of women among the authors has increased slightly to approximately 25% and the percentage of North American authors has declined to fewer than half. Again, North America and Western Europe still contribute the larger share of the 2/e authors but the growing representation of social and behavioral science authors outside the West is both noteworthy and encouraging.

Another important point is that the international scope of the project is much more pronounced than editors' and authors' current affiliations would lead one to conclude. (This would have been equally true in 1/e as well.) Consider, for example, Michiru Nagatsu, author of our article 03053 on the history of behavioral economics. Dr Nagatsu was born in Japan and retains Japanese citizenship but was educated at Exeter and the London School of Economics and Political Science and wrote his IESBS 2/e article while on a postdoctoral fellowship in Finland. Or Guillermina Jasso, area editor for Area Three. Jasso was born in the USA, received her PhD from Johns Hopkins, and is on the faculty at New York University. By any standard, she would count as a US sociologist in our compilations. Yet her parents were Mexican of Basque, Spanish, Portuguese, and Dutch origins; Spanish is her native language; over the course of her distinguished career, she has published with coauthors from Germany, India, Israel, Mexico, the Netherlands, and Sweden; and she holds a permanent research fellowship at IZA, the Institute for the Study of Labor, in Bonn, Germany. Scoring her as 'USA' scarcely does justice to her biography or to the international perspective she brought to the editorial task.

What is true of author Nagatsu and editor Jasso is true in degrees of virtually the entire roster of IESBS participants. If one includes place of birth, citizenship, where educated, sites of research, visiting appointments, sites of fellowships, honorary professorships, invited lectures, and on through the list of highlights in a modern academic career, it is safe to say that every nook and cranny of the globe (save, possibly, Antarctica) is represented somewhere in the biographies of IESBS authors and editors. The true measure of internationalism, in short, is not so much where people come from or where they currently are, but rather the extent to which they bring a sensitivity and commitment to cultural and national differences into their work. Whether this was or was not realized in 2/e is for readers to decide.

Concluding Observations

Smelser and Baltes aspired in the first edition of this work to "assemble the whole range of knowledge – vast and complex as it is – of the social and behavioral sciences in one place." Since what does and does not qualify as 'social and behavioral science' is itself contested, it is not surprising that nearly every one of the market reviews commissioned by Elsevier to guide the development of the current edition noted content omissions in 1/e that reduced its usefulness and that needed to be addressed in a second edition. Critics can and no doubt will say the same about 2/e. I have already mentioned the nearly 800 articles that appeared on the 2/e Table of Contents at one time or another but that will not be found in the final product, either because agreeable authors could not be located or (less often) because agreeable authors never produced an acceptable article. And it is pretty easy to identify whole chunks of present-day social and behavioral science that are given short shrift, or no shrift at all, in this work – not because these chunks were judged to be unimportant but because limits of time, space, resources, and networks meant that some elements of the contemporary social science enterprise never came to our attention.

The social and behavioral sciences begin with what artificial intelligence guru Marvin Minsky once described as a "three pound computer made out of meat" – the human brain, which for all we know is the most complicated three-pound hunk of matter in the universe – and end with a thoroughly globalized culture and social structure that encompasses all aspects of our species' physical, biological, psychological, social, emotional, cultural, and spiritual lives. We are the most successful species ever to have inhabited the planet; we have colonized every inhabitable piece of dirt; our range extends everywhere; all the earth's resources lay at our command. To record all that has come to be known about human origins, evolution, language, culture, and social structure – everything we know about human emotions, identity, love, religion, family, economics, politics, domination, exploitation, and on through a very long list – would require orders of magnitude more volumes than the mere 26 volumes that comprise the present work.

We have come increasingly to the realization that what is social and human about our species is very intimately connected to our biological, genetic, and evolutionary inheritance. At the same time, the brain specifically and biological evolution more generally "cannot be viewed separately from the material, historical and

social circumstances that produce it" (Berntsen and Baker, 2015). As these authors put it, biology and culture are 'mutually constitutive.' Fifteen years ago, the editors of the first edition remarked on "ferment at the boundaries between the biological and the behavioral and social sciences." And while there are still important controversies, much of the ferment has yielded to cooperation as we are just now beginning to explore this endlessly complex web of interconnectedness between our biological and social selves. It is an easy and nearly inevitable conclusion, thus, that the third edition of the IESBS will contain a great deal more of the work being done at this intersection than 2/e was able to accommodate.

To conclude on a purely personal note, the 5 years I have spent working on this project produced many professional and personal gratifications, none quite so delicious as the certain knowledge that I would learn something new every single day. My work on 2/e exposed me to literature I never knew existed and to aspects of the social and behavioral sciences of which I was at best dimly aware. I can only hope that readers who come to these pages will find them as enriching as I have.

ACKNOWLEDGMENTS

A work of this scale is inevitably a communal enterprise involving many hundreds of editors, authors, reviewers, technical support people, colleagues, professional acquaintances, and friends who have provided input, advice, encouragement, and assistance over the past five years. Any listing is bound to be incomplete, so my apologies in advance to those who expected to be mentioned here but are not. Be assured that the slight is not intentional.

My negotiations with Elsevier about this project began early in 2010. By May of that year, I had committed to the project and have been working on it at varying levels of intensity ever since — often on weekends, during holidays, and whenever else I could snatch a useable chunk of time. So my first acknowledgment must be to my wife Chris for suffering through my five year obsession, always with understanding and affection, usually with good cheer. Chris is probably the only person in the world who is happier than I am that the project is now completed.

I must also acknowledge an enormous intellectual debt to the editors in chief of the first edition of the *International Encyclopedia of the Social and Behavioral Sciences*, Drs Neil Smelser and Paul Baltes (the latter now deceased). Dr Smelser was gracious enough to serve as Chair Emeritus of the project's International Board of Consulting Editors and to put himself at my disposal as, in his words, "a battle-scarred veteran." The basic intellectual structure of this work is adopted more or less wholesale from the Smelser—Baltes edition, with a few exceptions noted earlier in the *Introduction*. Without the original to serve as the starting point and blueprint, it is hard to imagine even embarking on such a task, much less bringing it to completion. Their edition was hailed as "the largest corpus of knowledge about the social and behavioral sciences in existence," which is to say that it formed an *extremely* solid foundation from which to build the work you now hold in your hands.

The first edition was organized into 39 sections overseen by a team of 53 section editors. The structure of the second edition is slightly different. It is divided up into 10 broad 'Areas,' each with an Area Editor overseeing the work of between four and eight Section Editors. In all, the second edition is thus comprised of the 10 Areas subdivided into 53 Sections; the 53 Sections were developed by a team of 76 Section Editors. So whereas Smelser and Baltes had 53 colleagues to help complete the work, I had 84 (two of the Area Editors also edited their own sections). On pages i-v in the front matter to this work one finds an Editorial Board list showing the Area Editors, Section Editors, Sections, names, and affiliations of the entire editorial team — a team whose dedication and effort in behalf of the project has vastly exceeded the rate of pay. A more helpful, productive, or delightful group of scholarly collaborators is difficult to imagine.

What readers see in the listed Editorial Structure of the work is the *final* editorial team as it existed when the work went into production. As would be expected in a project of this duration, there was considerable turnover within the team as the project developed and as death, competing demands, and general indifference all took their toll. I am grateful, nonetheless, to everyone who agreed, at least initially, to participate in the project, whether or not they were able to stay involved to the very end.

Susan Hanson (Geography) and Ulf Hannerz (Anthropology) are owed a special note of thanks because, of the 53 Section Editors involved in the first edition, these are the only two who agreed to reprise their roles in the second. (Both also wisely requested and received coeditors to carry part of the load.) Persuading people to serve who had no real idea what they were getting into was challenge enough, but these two suffered through 1/e and were willing to do it all over again for 2/e. And for that, I am especially grateful.

Many of the editors benefitted from the assistance of colleagues and graduate students at their various institutions. There was no mechanism built into the editorial process to keep systematic track of this

assistance and so the listing below is certain to be incomplete. But I can at least acknowledge those of whom I am aware who contributed time and intellectual energy to the effort: Liam Morton and Andrea Livingstone (Psychiatry); Jennifer O'Connor and Alana Dorris (Applied, Industrial and Organizational Psychology); Jen Hanis-Martin (Sexuality); David Budde, Annette Stimmer, Nikolas Ott, and Franziska Pfeifer (Institutions and Infrastructure of Social and Behavioral Sciences); Matthew LeDuc and Scott Freeman (Contemporary Cultural Concerns); and Simone Dudziak (Public Policy). To those named, my thanks. To those omitted, my apologies.

A special note of thanks to Dr Donald J. Barrett. Don was originally recruited to develop an entirely new section of the second edition on Gay, Lesbian, Bisexual, and Transsexual Studies, completed the section in short order, then e-mailed me to ask if there was anything further he could do to be helpful. Consequently, he took a major hand in developing the section on Biographies and was quite helpful with many other sections too. He appears in the Editorial Structure both as a Section Editor and as a Senior Editorial Associate to acknowledge his yeoman service to the entire enterprise. Also listed as a Senior Editorial Associate is my colleague Dr Amy M. Donley, who has been with the project since the very beginning and who, more than once, was all that stood between me and madness. I am proud to count them both as colleagues, collaborators, and friends.

I am also pleased to acknowledge Don Barrett, Andreas Hess, Harry Whitaker, John Berry, Barbara Miller, Scott Bentley, and Claire Byrne for their incisive and helpful commentary on previous drafts of the Acknowledgments and Editor's Introduction.

The project's International Board of Consulting Editors, chaired by Smelser and Dr Peter Marsden of Harvard University, was formed late in 2011 as a 'sounding board' to be used by the Area and Section Editors in searching for topics and authors and to help push for greater internationalism in our coverage. As it turned out, several members of this Board also stepped up to write entries in their areas of expertise. The composition of this Board and the affiliations of the consulting editors (as they were when the Board was first formed, not necessarily as they are today) are as follows: Neil J. Smelser, *University of California, USA*; Peter V. Marsden, *Harvard University, USA*; Ronald F. Abler, *International Geographical Union, USA*; John Bacon-Shone, *University of Hong Kong, China*; Roberto Briceño-León, *Universidad Central de Venezuela, Venezuela*; Roel Bosker, *Rijksuniversiteit Groningen, The Netherlands*; Michael Burawoy, *University of California, Berkeley, USA*; Nestor T. Castro, *University of the Philippines, Philippines*; Dalton Conley, *New York University, USA*; Freek Cronjé, *North West University, South Africa*; Scott Davies, *McMaster University, Canada*; Abdul Rahman Haji Embong, *Malaysian Social Science Association, Malaysia*; Joan-Maria Esteban, *Barcelona Graduate School of Economics, Spain*; Robert S. Feldman, *University of Massachusetts, USA*; Sari Hanafi, *American University of Beirut, Lebanon*; Gudmund Hernes, *Norwegian Business School, Norway*; Sheila Jasanoff, *Harvard University, USA*; Tim Jensen, *University of Southern Denmark, Denmark*; Colin Jones, *University of London, UK*; Nadezhda Lebedeva, *Higher School of Economics; and National Research University, Russia*; Miklós Lévay, *Eötvös Lorand University, Hungary*; Dinka Marinovic Jerolimov, *Institute for Social Research, Croatia*; Laurie M. Joyner, *Rollins College, USA*; Ferenc Kiefer, *Hungarian Academy of Sciences, Hungary*; Pan Suk Kim, *Yonsei University, South Korea*; Katsuya Kodama, *International Peace Research Association; and Mie University, Japan*; Allan Lavell, *Facultad Latinoamericana de Ciencias Sociales (FLACSO), Costa Rica*; Jake Lynch, *University of Sydney, Australia*; Cecilia Mabragana, *Consejo Nacional de Investigaciones Cientificas y Tecnicas (CONICET), Argentina*; William McBride, *Purdue University, USA*; Ishwar Modi, *University of Rajasthan, India*; Leonardo Morlino, *School of Government, Italy*; Melvin L. Oliver, *University of California, USA*; Angela M. O'Rand, *Duke University, USA*; Kenneth Prewitt, *Columbia University, USA*; Thilo Rehren, *University College London Qatar, Qatar*; Colette Sabatier, *Université Victor Segalen, France*; Philip Schofield, *University College, UK*; Rainer K. Silbereisen, *University of Jena, Germany*; Chamhuri bin Siwar, *National University of Malaysia, Malaysia*; Tom W. Smith, *World Association for Public Opinion Research, USA*; Catalina Smulovitz, *Universidad Torcuato Di Tella Miñones, Argentina*; Philip Spinhoven, *Leiden University, The Netherlands*; Sukhadeo Thorat, *Indian Council of Social Science Research, India*; Nigel Thrift, *University of Warwick, UK*; John R. Townshend, *University of Maryland, USA*; Gisèle Yasmeen, *Social Sciences and Humanities Research Council of Canada, Canada*.

Searching for an editorial team to represent every social science discipline and every region of the globe quickly exposed the deficiencies in my personal network, so I am indebted to a very large number of scholars around the world for calling names of prospects to my attention, allowing me to drop their names in the recruitment effort, or otherwise helping me find people with the expertise and commitment required for the job. In most cases, this is a list of people who were invited onto the editorial team in some capacity,

demurred, but made valuable suggestions about others to contact. In several cases, people are listed because they engaged me in intellectual discussions about the structure, format, and even advisability of this work, or simply replied to a cold-call e-mail in pleasant, kind, helpful, or informative ways. Again ignoring the risk of omission, my sincere personal thanks to those named below for their contributions large and small to the final product:

Doug Anderton, Juri Allik, George Armelagos, Susan Ayers, Amanda Baumle, Janeen Baxter, Jess ben-Habib, Joao Biehl, David Blanchflower, Hans-Peter Blossfeld, Jason Boardman, Dorret Boomsma, Roel Bosker, Henry Brady, Martin Bulmer, Craig Calhoun, Miguel Centeno, William Cockerham, Mark Nathan Cohen, Amelie Constant, Simon Cottle, Connie Citro, Eileen Crimmons, James Curran, Scott Davies, Donatella Della Porta, George Downs, Francis Dodoo, David Dozois, Sonja Drobnick, Jaap Dronkers, John Dryzek, Riley Dunlap, Lauren Edelman, David Elesh, Paula England, Nancy Eisenberg, Geoffrey Evans, Miriam Faust, Robert Feenstra, Marcus Feldman, Stanley Feldman, Ronald Fischer, James Fowler, Jeremy Freese, Angela D. Friederici, Michael Frumpkin, Masahisa Fujita, Nicole M. Gage, Nancy Gallini, Rosemary Gartner, Morton Ann Gernsbacher, Robert Goodin, John Grattan, Lance Gravlee, David Greenberg, Wendy Griswold, Melanie Guldi, Monica Das Gupta, Peter Hatemi, Robert Haveman, Karen Heimer, John Hibbing, Sarah Blaffer Hrdy, Sheila Jasanoff, Kelly Kadera, Cigdem Kagitcibasi, David Kavanaugh, Roger Keil, Byungkook Kim, Rob Kitchin, Jack Knight, Lyle Konigsberg, Candace Kruttschnitt, Helen Ladd, Phillip Lane, Graeme Lang, Janet Lauritsen, Ashley Leeds, Evelyn Lehrer, Richard Lerner, David Lewis, Tim Liao, Tom Linneman, Norman Long, Karen Lyons, Ruth Mace, Gary Marks, Herbert Marsh, Karl-Ulrich Mayer, Lorraine Mazerolle, Rose McDermott, Susan Michie, Harry Minas, Peter Miller, S. Phillip Morgan, Victor Nee, Vin-Kim Nguyen, Paul Nieuwbeerta, Helga Nowotny, Howard Nusbaum, Claus Offe, Thomas Ollendick, Joan Orme, Dennis O'Rourke, Michael Overington, Catherine Panter-Brick, Susan Parnell, Deborah M. Pearsall, Gerard Pfann, Jon Pierre, Mike Ping, Jennifer Platt, Ken Prewitt, Cathy Price, Jill Quadnagno, Charles Ragin, Thilo Rehren, Ben Rosamond, Bo Rothstein, Beth Rubin, Heinrich Sauer, Peer Scheepers, Ralf Schwarzer, Moshe Semyonov, Michael Shanahan, Sara Shostak, Alan Sica, Rainer K. Silbereisen, Beth Simmons, Catalina Smulovitz, Michael Sobel, Diane Stone, Jill Stephenson, Rafe Stolzenberg, Miron Straf, Richard Swedberg, Alan C. Swedlund, Sidney Tarrow, Jacques-Francoise Thisse, Stefan Timmermans, Florencia Torche, Erik Tsang, Judy Treas, Billie Turner, Cees van der Eijk, Paul van Lange, James Vaupel, Karin Wahl-Jorgensen, Mitchell G. Weiss, Neil Whitehead, Pamela Wilcox, Bjorn Wittrock, Cornelia Woll, Gisele Yasmeen, and Barbie Zelizer.

Gratitude is owed as well to the many colleagues at Elsevier who contributed to the production of this volume. My first debt is to Claire Byrne, the project's Content Project Manager and the head of the Major Reference Works (MRW) team that managed the day-to-day *Sturm und Drang* of the project: aggrieved, confused, or delinquent authors, missed deadlines, testy and intransigent editors, and the often-maddening work style of the Editor in Chief. I am sure there were days when Claire wanted to tear her hair out, but to external appearances, she was an island of calm in a sea of turmoil. She was also exceptionally good at her job.

Claire's MRW team comprised Richard Berryman, Will Bowden-Green, Esmond Collins, Mark Harper, Sam Mahfoudh, Mike Nicholls, Gemma Tomalin, Joanne Williams, and Marise Willis. No matter what issue or problem I faced, one of these fine, capable people was always available to step up with a solution, invariably offered in a spirit of cooperation and good cheer. They have been to IESBS 2/e what tech support is to the modern computerized office. Getting this work completed without their help is inconceivable.

Thanks also to the succession of Elsevier's Acquisitions Editors who managed the finances and internal politics of the project: to Scott Bentley, whose gentle suasions pulled me into the project in the beginning; to Karen Maloney and Peter Labella who ran the show in the middle period; and to Lisa Tickner who was in charge at the very end. These are the people on the front line in the endless war between the publisher, who wants things done now and at minimal expense, and the Editor in Chief, who was always asking for more time and more money. The many dozens of amicable compromises necessary to bring the project to completion were all ably negotiated by Scott, Karen, Peter, and Lisa, and for that, I am grateful indeed.

The University of Central Florida and its Department of Sociology have provided a congenial home for the project. My thanks in particular to Dean Michael Johnson; to the current and former chairs of my department, Jana L. Jasinski and Libby Mustaine; to my faculty colleagues Liz Grauerholz, Phillip 'Hutch' Pollock, Bruce Wilson, Melanie Guldi, Stacy Barber, Tosha Dupras, and John Schultz; and to current and former graduate students Thomas Hall, Sara Strickhouser, Betsy Swart, Jordana Navarro, Marie Gualtieri, Shannon Simone, and Shannon Frey.

And most of all, my sincere thanks to the many thousands of authors whose work this is. When comparing the quality of the work contained within these pages to the authors' honoraria, it is obvious that IESBS 2/e is an act of collective charity by our authors to the disciplines they represent. It is my pleasure to thank our authors on behalf of the global social science community.

James D. Wright

GUIDE TO USING THE ENCYCLOPEDIA

Structure of the Encyclopedia

The material in the Encyclopedia is arranged as a series of articles in alphabetical order.

There are four features to help you easily find the topic you are interested in an alphabetical contents list, cross-references to other relevant articles within each article, subject classification index, and a full subject index.

1. Alphabetical Contents List

The alphabetical contents list, which appears at the front of each volume, lists the articles in the order that they appear in that volume of the Encyclopedia. It includes both the volume number and the page number of each article.

2. Cross-references

All of the articles in the Encyclopedia have been cross-referenced. The cross-references, which appear at the end of an article as a See also list, serve three different functions:

a. To draw the reader's attention to related materials in other articles.
b. To indicate material that broadens and extends the scope of the article.
c. To indicate material that covers a topic in more depth.

3. Subject Classification Index

This index appears in Volume 26 and groups articles under subject headings that reflect the broad themes of Social and Behavioral Sciences. This index is useful for making quick connections between articles and locating the relevant article for a topic that is covered in more than one article. Under some section headings, you will find subheadings, if it is appropriate for the articles in a subject area to be grouped into more specific subareas.

4. Contributors

At the start of each volume, there is list of the authors who contributed to that volume.

5. Index

The index appears in Volume 26. The index includes page numbers for quick reference to the information you are looking for. The index articles differentiate between references to whole article, a part of an article, and a table or figure.

Solidarity: History of the Concept

Patrick Cingolani, Bâtiment Olympe de Gouges, University-Paris Diderot, Paris Cédex 13, France

Abstract

The modern sociological concept of solidarity originated with the French philosopher and politician Pierre Leroux and took on its definitive modern meaning during the French Third Republic as influenced by the progressive thinking of the eminent *homme de gouvernement* Leon Bourgeois. The term refers generically to unity or agreement of outlooks and behaviors among persons of like interests, as in 'working class' solidarity. In sociology, solidarity is understood to be essential in the success of any social movement. In this sense, the concept of solidarity came to be central to the thinking of many social commentators and critics, among them de Maistre, Comte, Proudhon, Marx, Bakunin, and others.

Introduction: Solidarity and Society

The history of *solidarity* is ridden with paradox: it is embedded in the ambivalent ties that bind the members of a community together in active or passive ways. In ancient Rome, the *gens* was held accountable for personal debts contracted by any of its members: it was expected to redeem those who were made prisoners, as well as to pay for the fines of the condemned. A form of solidarity was thus established by law between the person and the *corps* to which she or he belonged. The clan-based structure, with all its sacrificial logics or vendettas, is an institution of solidarity. Traces of this are enshrined in contemporary law: creditors may act 'in solidum' and groups may be jointly and severally liable for one of their parties' debts. Ambivalence also pervades the historic intellectual momentum that the word 'solidarity' was to acquire in the wake of the French Revolution and its successive readings. It resurfaces in the writing of the counterrevolutionary theocrat and traditionalist Joseph de Maistre, in connection with the notions of *solidarity in crime* and compensation for revolutionary executions, and also in the work of the Saint-Simonian philosopher and politician Pierre Leroux, who furthered its recognition as a theory and declared: "I was the first to borrow the notion of solidarity from the lawmaker (…) My wish is to replace Christian charity by Human solidarity" (Leroux, 1863). Focusing on sacrificial rituals, Maistre underscored 'human degradation' as evidence of human unity; Leroux, for his part, elaborated on the human need for friendship, on the grounds that one has only a half-life, "the other being part of humankind" (Maistre, 1854).

There may be doubts as to whether Leroux actually coined the term *socialism*, but one can hardly deny his unique contribution to the modern usage of the neologism *solidarity*. The word was extensively used in one way or another by a number of nineteenth- and twentieth-century social thinkers. It was eventually revisited not only by Fourierists and positivists, with Auguste Comte and Emile Littré, but also by mutualists, with Proudhon; internationalists engaged in a labor movement inspired largely by Proudhon, Marx, or Bakunin; and lastly, by solidarists. It was inscribed, with varying degrees of success, in the framework of the antinomy established by Leroux between the recognition of the social fact and the refusal to sacrifice the individual to the community. Yet it was mostly through the thought and policy of the Republican movement and the institutional project that led up to the creation of the French Third Republic that the concept was eventually to unfold as a sociological category on the public sphere, around Léon Bourgeois' notion of solidarism, which acknowledged our mutual interdependency even as it fully legitimized the individual.

Solidarity: From Archaism to Modernity

The sense of solidarity was essential not only for maintaining unity within the clan but also for ensuring harmony and pacified interaction between different clans. This is borne out by anthropological studies on gift exchange mechanisms, such as the *Potlatch* practiced by the *Kwakiutl* in Northwestern America, or the *Kula*, which involves significant intertribal exchanges throughout the Trobriand Islands on New Guinea's West Coast. Research conducted by Bronislaw Malinowski (1872–1942) and Franz Boas (1858–1942), and interpreted by Marcel Mauss (1872–1950), underscores the disinterested nature of such mechanisms. In cultural and religious frameworks, they formalize pledges and counterpledges to give, to receive, and to give back for the purpose of building and fostering networks of solidarity. What is exchanged is not only useful economically but also consists "above all *of courtesies, entertainment, rituals, military assistance, women, children, dances and feasts*" (Mauss, 1925b). The circularity of giving, by institutionalizing a commitment to solidarity, seems to have provided humankind with its earliest form of pacification. The archaic gesture of giving is visibly perpetuated in major religious traditions and civilizations, including ancient Greece, as described by Aristotle (384–322 BC). No less surprising are the popular practices and traditions observed in contemporary societies, which cultivate a strong relationship to spending as an expression of social interaction.

The unity of humankind is thus underpinned by a number of religions: the comments of Augustine (354–430) on the Old and New Testaments in the *City of God* remind us, for instance,

that all men were naturally brothers through Adam, even before they reached supernatural brotherhood in Christ. In fact, charity and hospitality are underscored in most religious texts, ranging from the holy scripture of ancient India, which offers a number of rules on hospitality and giving, to the book of Leviticus with its well-known commandment to "Love your neighbor as yourself." A sura in the Qu'ran instructs the faithful to "…obey and spend, it is better for your souls." The arguments and principles originally outlined by Aristotle for friendship in the Greek *polis* have permeated the West's political heritage as a whole. Affluent Greeks were subjected to mandatory standards of redistribution of wealth, mainly to support galleys for defense purposes, religious ceremonies, and associated theatrical events. But the conceptualization of such issues by Aristotle was aimed at taking interpersonal friendship to a collective, political level in order to ensure harmony within the community. To lawmakers, he explained, harmony seems to matter more than justice, for it is a determining political factor. Giving and redistribution establish bonds of mutual obligation among citizens, enabling the *polis* to find balance in a middle ground. Aristotle sees the practice of redistribution as a way to counter the extremes that challenge democratic societies, faced with balancing the demands of large impoverished populations with the excessive power of the wealthy few. Further, to the best interests of society, tributes paid to patrons and donors combine with honorable distribution of compensatory goods and services to the poor as symbolic rewards for those who contribute to ensuring economic balance and collective peace.

However, giving as mediation is not only found in the great theological and philosophical treatises on friendship but is also prevalent in our very midst, among the peoples of the world. Hospitality and in particular the feasts that we hold in the framework of alliances, the presents and the costly expenditures surrounding rites of passage, marriage, and birth are embodiments of the selfsame give and take through which humans have managed to engage with each other, generating the sort of precontractual inclination that giving provokes in the other, to create and to foster the bonds of solidarity. In his renowned essay *The Gift* (1925b), Emile Durkheim's nephew Marcel Mauss suggested we "return to the old and elemental," following a philosophical tradition in which solidarity and, more generally, mutual assistance, emerge as crucial wagers of modernity. "To return to the old and elemental" is to reclaim certain ancestral and universal practices of solidarity, and to adapt them to the needs of the rising twentieth century, by means of novel and thoughtful practices and modes of redistribution.

In many ways, however, it was the French Revolution which gave its momentum to the narrative and subsequently scholarly discourse on solidarity per se. To be sure, the French Revolution was viewed by some as a radical crisis or rupture of the social bond. To others, however, it appeared as an opportunity to rethink that selfsame bond in light of the 'in-solidarity' (the French neologism *insolidarité* is found in Fourier and Proudhon) that comes with free trade. Inspired by counter-revolutionary assessments, Auguste Comte (1798–1857) progressively regards the French Revolution as a source of 'Western anarchy.' Others, however, Leroux or Proudhon, for one, welcome it as a step toward a novel sociability, namely, an enhancement of justice. Comte sees historical continuity in the exhortation of a form of intergenerational solidarity that would, as such, run deeper than 'solidarity with contemporaries.' Opting for subordinating the present to the past and progress to order, he criticizes the 'uprising of the individual against the species' and suggests, in the long run, that duties should substitute rights. Sensing the hazards in authoritarian communism or Comte's Sociocracy, Leroux is careful to embed his solidarity in a dialectic between civil society and the State, and a full recognition of the individual. Proudhon, wary of any positivist tendency to 'absorb the individual into the agency,' tries for his part to reconcile, through mutualism, the social property and the workers who contribute to its development. "That is what our solidarity consists in," he declares in his final opus: "we are all clients to each other, servants all" (Proudhon, 1865). Heirs to Saint-Simonian critiques of private property's contingency on society's state of development, they each impugn, in their varied ways, what they see as stumbling blocks to general welfare and collective prosperity in the uneven forms of private property and inheritance. Following Proudhon, Marx, and the larger share of socialist and liberal thinkers, the labor movement denounces private ownership of the means of production and makes unity a major aim of its activism. It had every reason to embrace solidarity, as it needed to overcome divisive market laws and management practices as well as to forge coalitions among trade unions, not only for strikes but also for the broader struggle against capitalism. What emerges at first as *class solidarity* would ultimately lead to the movement's internationalist project and its renowned slogan: 'Workers of the world, unite!'

Solidarity and the Republic

Still, it took more than the labor movement and its theorists, all the more concerned with justice, equality, or social emancipation to bring the concept of *solidarity* to its ultimate consequences. It was more likely the development of *solidarism*, in close connection with the French Third Republic, which provided the needed intellectual stimulus for the concept to thrive under State jurisdiction. It was as though it had to take yet another historic turn in order to prove the full range of its coherence and practical effectiveness. It required a combination of intellectual, institutional, and political factors, which finally materialized at the founding of the Radical Party. To be sure, the Republican Party had directly inherited the sociological theories of positivism, owing mainly to the influence of Comte's disciple Emile Littré (1801–81) and of positivist-minded politicians such as Jules Ferry (1832–93) and Léon Gambetta (1838–82). And yet, it was the Radical Party which finally paved the way for solidarity to form as a concept, namely, around the personality and work of Léon Bourgeois (1851–1925), the theorist of radicalism and promoter of the notion of solidarism. A member of the French Parliament and a senator who served several terms as minster, Bourgeois is closely associated with the doctrine of solidarity. He revisited Comte's theory of continuity, but diverted it to a sort of individual personal development. From the positivist inheritance, he maintained the belief in the contingency of the past: no economic production, no scientific or technical innovation is

possible without the legacies of history. "It has rightly been said that humanity is made of more dead than living; our body, the products of our labor, our language, thoughts, Institutions, art, all are inherited, a treasure slowly accumulated by our ancestors" (Bourgeois, 1896). In this sense, we all have a social debt, or duty, to pay. This does not imply, as in Comte, however, a subjection to the Great Being. Through taxation and institutions that redress social inequalities, individuals repay their debt and recover their freedom. If the individual is obliged to society, however, society is no less responsible to the individual and thus for correcting social discrepancies that result from arbitrary contingencies such as individual birthrights and wealth. Whatever his or her social background, however, "the individual's responsibility is not absolute"; much to the contrary responsibility for the 'individual's debt' falls upon society, by virtue of the unequal birthrights and entitlements that are effective in its midst. It is society's duty to "make the effort" that enables individuals to rise above their conditions (Bourgeois, 1902). Solidarism gives rise to a full-fledged rationale for the legitimization of a range of institutions, from education to social security through progressive taxation, all seeking to settle the outstanding debt by contributing to individual personal development. Even though it respects private propriety, solidarism thus justifies any State intervention that strikes a balance between capital and labor, compensating, by force if need be, for the unfairness that results from capitalist excess. "Collectivization is not a goal of the system of solidarity (…) The doctrine of solidarity is to redeem freedom and individual propriety; it is the very justification for the freedom to own property" (Bourgeois, 1902). Underpinning the major premises and conclusions of the solidarist doctrine is a full range of theories on the subject of solidarity. For, even if Bourgeois is above all a politician and fully engaged in public life, numerous scholars have contributed to developing the concept of solidarity: a constellation of sociologists, economists, and philosophers led by Charles Gide (1847–1932), Emile Durkheim (1858–1917), and Alfred Fouillée (1838–1912).

Charles Gide, a lawyer and professor of social and political economics, at the Universities of Bordeaux and then of Montpellier (France), was a founder and an active member of the cooperative movement. His commitment and teachings contributed significantly to the elaboration, if not to the foundation, of the concept of solidarity. As early as 1890, his book *Quatre Ecoles d'Economie Sociale* laid down the groundwork for a new school of economics based on solidarity, which was further elaborated in his final lectures at the Collège de France, published in 1932. His work puts the concept in a historic perspective and engages a dialogue with various theorists – from Comte to Bourgeois. It is notable, for our purposes, that he draws a parallel between solidarity and charity, explaining, to that effect, that "the one who acts out of solidarity, such as the trade-union leader, the mutualist, the cooperator, may expect (…) in return (…) a higher economic regime in which s/he may find greater independence or security, or a higher standard of living. He would trade off a present good for a possible one; he would sacrifice a bit of his individual self to enhance his social self" (Gide, 1932, p. 199). In contrast, charity expects nothing in return. State and private institutions promote solidarity: for women and mothers, children and infants, childcare, as well as housing for the disadvantaged. Charity, for its part, is likened to a sentiment that is no doubt likewise concerned with justice, but constantly strives to increase it by expanding "the concentric circle of love to the same extent" (Gide, 1932, p. 214).

As for Emile Durkheim, who founded the French School of Sociology, he was deeply committed to the French Republic's political and institutional system. As professor of education and social sciences in Bordeaux, and later sociology at the Sorbonne, Paris, he developed his own theory of solidarity through constant dialogue with contemporaneous scholars. In *The Division of Labor in Society* (1893), he bases his sociological theory on a social philosophy that spans the entire nineteenth century, insisting that the whole is greater than the sum of its parts and that the social should prevail over the individual. Durkheim distinguishes the 'mechanical solidarity' of tribal groups from the 'organic solidarity' of contemporary societies: whereas the former is based on sameness and normatively contingent on the collective consciousness, the latter rests on division of labor, specialization, and recognition of the individual's freedom of opinion: its establishment appears to him to be 'anomic,' or conditioned by provisional circumstances. Several major commentators have noted, however, that he distanced himself from his earlier works and only returned to his theory of solidarity after further rethinking the issues of collective consciousness and moral authority. In fact, it was thanks to a later theory on spending, which was taken up by his nephew Marcel Mauss, that matters of giving and solidarity made their way back into his work. This is particularly evident when Durkheim shifts his focus from industrial to religious issues. Focusing on aboriginal Australian religious practices such as inebriation and collective spending, his *The Elementary Forms of Religious Life* (1912b) places 'the social fact' and its autonomy in a new light: "When there is close interaction and mutual influence among individual consciences, the resulting synthesis gives rise to a novel consciousness. Drawn by the collective mainstream, the individual rises above his/her own self-interest and dedicates him/herself entirely to the common purpose" (Durkheim, 1924, p. 133). Ultimately embodied in religious fervor, the social fact generates, by virtue of its desirability and capacity to overwhelm, such deep-seated feelings of solidarity and brotherhood that the Christian notion of "human equality and fraternity seems to us today to leave too large a place for unjust inequalities" (Durkheim, 1912b, p. 427). However, Durkheim contributed more to backing the notion of solidarity scientifically than to promoting its practical implementation. Like Charles Gide, he correlates and assesses solidarity, justice, and charity. Seeking to provide a scientific account of the conditions of collective generosity in a powerful and novel elaboration of the moral fact, he reaches the conclusion that charity has become, in early twentieth-century societies, an obligation that gives rise to the foundation of public institutions.

Alfred Fouillée, the third theorist, was unique not only for complementing the notion of solidarity with that of 'social property' but also for making a compelling argument on behalf of the specific domain of the State. He recalls the Saint-Simonian emphasis on the evolving nature of ownership and uses it to sound out the law. His aim is to uncover its scientific principles and to give it a practical dimension. Accumulated

productions condition the activities and development of those who are living and partaking in the vast process of transmission, which regulates the conditions for production and life in contemporary societies: "All the books that are read today are still printed by Gutenberg" (Fouillée, 1884, p. 21). In Fouillée, we find a third way between the individualism and socialism, privatization of the public good and collectivism, which is characteristic of radical republicanism. "Since the product of labor is common to the individual and to society, property theoretically contains both an individual and a social part" (Fouillée, 1884, p. v). The State has the right and the duty to intervene in the circulation of materials, goods, information, and people: "roads, postal and telegraphic services, currency – all of which really pertain to the public-service" (Fouillée, 1884, p. 39). The State acts in the name of justice to redress social discrepancies. "It plays a positive and brotherly role, striving to remedy the bad for the good" (Fouillée, 1880). The State must look after insurance plans: life, old age, health, and unemployment. But such plans, like primary education and other Republican Institutions, are not just entitlements. They are also duties with which all citizens must comply. 'Every sort of freedom entails a correlative duty.' In the course of his work, Fouillée provided pioneering insight into the instrumental role of the modern social State in the process of decommodification of social relationships, such as was recently developed by G. Esping-Andersen (Esping-Andersen, 1990). Such State mediation checks the subjugation of people to competitive market constraints, thus ensuring their personal development. For Fouillée, leaving the individual to cope with coalitions, corporations, and holdings is tantamount not only to depriving her or him of the means to defend her or his interests but also to denying him or her freedom from the pressures of the market, discrimination, and cronyism. State intervention aimed at preventing work hazards, ensuring sanitation and mediating social disputes in the workplace, as well as regulating pensions thus contributes to individual autonomy and emancipation from dominating forces. "State intervention in the workings of the economy is justified by law and the common interest (…) there is nothing socialistic about it." As Robert Castel (1933–2013) points out, Fouillée's notion of 'social property' prefigures the emergence of a 'labor society,' as the idea of a statute for workers was beginning to form a veritable social framework for solidarity (Castel, 1995).

Although solidarity was forcefully conceptualized and proclaimed around a French political movement, France was neither the first to implement social policy nor to establish a system of social security. To be sure, the French notion of national public assistance predates Beveridge's *Welfare State*. But the so-called 'social insurance' was implemented in other European countries prior to France. Its 1880 enactment in Bismarck's Germany was, nonetheless, expressly concerned with legitimizing an undemocratic State and instrumentalizing the social arena for political ends. Wiliam Beveridge (1879–1963), whose name is inextricably bound to the Welfare State, had started, for his part, by theorizing the notion of insurance, on the basis of Webb's social reform project. His 1942 proposal targeted the five giants that stood in the way of reconstruction: deprivation, illness, ignorance, lack of hygiene, and idleness (Beveridge, 1942).

Solidarity throughout the World

Solidarists did not just conceptualize and construct a pacifying social State at the national level. Many of their most prominent members, Léon Bourgeois for one, also militated for peace and envisioned a League of Nations that would promote a worldwide legal framework and socioeconomic harmony. Another member of the cooperative movement was Albert Thomas (1878–1932), who contributed to the creation of the International Labor Organization. He delighted in the idea that the League of Nations' Global Compact should foster 'genuine international solidarity.' The solidarists' awareness of interrelationships and attachments enabled them to grasp economic globalization processes as well as sanitation and communication issues. In 1925, Mauss had been alarmed by his visit to Bolshevik Russia and taken stock of a disastrous World War that had decimated Europe's youth. Reflecting on reconciliation and international peace in an era of rising communism and nationalism, he evokes the metaphor of King Arthur's Round Table: "Peoples, classes, families and individuals may become rich, but they will not achieve happiness until they can sit down like the knights around their common wealth. (…) Happiness is to be found in the prevalence of peace, in the rhythm of communal and private labor, in wealth amassed and redistributed, in the mutual respect and reciprocal generosity that education can impart" (Mauss, 1925b).

Twentieth-century communism is, nonetheless, unavoidable as a social movement that placed its full range of experience under the mantle of internationalism. Emblematically, the Soviet Union would identify its national anthem with the 'internationale' composed by French musician and poet Eugene Pottier. That internationalism, beyond its historical mutations, its betrayals in the name of State and, finally, its totalitarian deviations, kindled and constituted the ideal revered by millions of workers and peasants throughout the world. In the 1960s, it acquired renewed momentum through the support extended by Western youth in large urban centers to colonized peoples and the impugnation of imperialist practices in a number of the world's developing countries, notably in Africa, South East Asia, and Latin America. Outside from its institutional, republican, acceptations, the word solidarity had never been as visible as it was in the internationalist dimension of the 1960s. Far from any sentiment of compassion or charity, what emerged from this vision of unfairness and exploitation of 'Third World' resources and workforces was clearly a political sense of solidarity with the oppressed peoples of the world. This would eventually revive a certain degree of sympathy for the cause of compatriot laborers in metropolitan centers. The peoples of Asia, Africa, or Latin America, while struggling for their independence, had also joined the assembly lines of Europe and North America.

Since the nineteenth century, the promotion of solidarity has worked in a tension between an institutional pole, exemplified by solidarism, and an activist pole, which, albeit quite diversified, is somewhat emblematized by twentieth-century Marxism. This is still the case today, as solidarity is once again shored up by social movements. Solidarity has been reclaimed by various international social forums in their struggle against market hegemony and the alienating effects of the plutocratic forms of corruption challenging democracy today. But it is even

more spontaneous in the various collective demonstrations against financial speculation or the effects of the subprime crisis. A shared sense of indignation has emerged in the wake of the collective drama that has impoverished or indebted segments of the labor and middle classes. Pamphlets and books by *indignados* in Spain or actors of Occupy Wall Street in North America likewise proclaim the collective value of solidarity. "We are the 99" does not just reflect the increasingly gaping inequality between the large majority and the affluent few; it is also translates a common experience and a solidarity of experiences. The various 'occupations' have worked simultaneously as ways to participate transparently in public life and to live together, in solidarity, rejecting the constraints of money and domination. They are demonstrations of goodwill and solidarity in response to levels of exploitation and greed that were unparalleled in the 1960s. The Spanish pamphlet ¡*Democracia Real Ya!* stresses that "equality, progress, solidarity, free access to culture, environmental sustainability and development as well as people's welfare and happiness are the priories of every advanced society." Those who witnessed 'Occupy Wall Street' saw hundreds of people coming together and making decisions with no management structure, "driven only by principles and solidarity."

We will have to wait and see whether these trends are part of a sustainable dynamic and not just transitory jolts and short-lived rebellions. But chances are the globalized economy will put the ideal of solidarity in the political spotlight again, this time on an international scale. The dynamic of international exchanges tends to nourish a feeling that we are all part of a single world. It has intensified cooperation, bonded people together, and encouraged political rapprochement through solidarity against those who unduly profit from informational asymmetry and violate national and international laws and regulations. In addition, the lurking threats of climate change, evidence of our collective involvement in a range of ecological mechanisms with imminent dangers and planetary consequences, can only be checked through competent institutions operating on a world scale and in a spirit of solidarity. The conflict dynamic that is stirred by confiscation of knowledge and discoveries, or the abuse of public domains and collective property for the sole benefit of a privileged few, also continues to act as a lever for collective solidarity. The risk of ecological disaster summons the idea of humanity – its common history and fundamental responsibility to future generations – to the forefront of today's collective dynamics. One can only hope that this can result in an institutional framework for solidarity, to coordinate its endeavors, above and beyond particular aspirations and projects, denouncing and correcting persisting inequities among and within various segments of the world's population.

Abstract

The discipline of sociology has taken the attainment of solidarity – in families, groups, organizations, and societies – as a principal outcome to be explained. This article compares normative, structural, and rational choice accounts of solidarity and discusses the likely paths of future research on this topic.

If economics is mostly about efficiency and growth, sociology is mostly about solidarity and social order. As economics suggests, competitive markets offer the best chance for an efficient allocation of productive resources. As sociology suggests, however, such markets can only arise in societies with sufficient order to produce and maintain stable property rights and other key public goods. Although both stability and growth are necessary to sustain any social formation over the long run, the disciplines of economics and sociology have largely developed in mutual ignorance, if not antipathy. This article suggests that progress has been made in the analysis of solidarity by integrating the two perspectives.

Solidarity – the binding of individuals into a cooperative collectivity on the basis of compliance with normative obligations – is an emergent attribute of groups that facilitates collective action and social order. The modern origins of the concept date from the beginnings of sociological theory. There are three leading theoretical perspectives on the emergence of solidarity. On the *normativist* view, solidarity is most likely to develop among individuals who share fundamental values, such as those promulgated in religious, ethnic, or national groups. On the *structuralist* view, solidarity arises from the sharing of common material interests as occurs, for example, among the members of social classes, ethnic groups, and genders. On the *rational choice* view, it owes to neither of these kinds of conditions; rather, it is a function of dependence and control mechanisms.

Since social order and collective action are the alpha and omega of classical sociological theory, solidarity has always been a central concept in sociology. The concept came to the fore following the changes wrought by the development of industry and the rise of market economies. Although they were unjustified in doing so, most classical social theorists regarded social order in agrarian communities as unproblematic. In their stylized view, such communities were technologically and demographically stagnant and uninvolved in long-distance trade. Given these assumptions and barring exceptional circumstances – such as those resulting from exogenous events such as wars or massive epidemics – social mobility would be minimal and most children would be destined to recapitulate the social lives and fates of their parents. As agrarian communities tended to offer relatively little scope for individualism, the attainment of solidarity was viewed as relatively unproblematic. According to Ferdinand Tönnies (1887), such communities (which he termed *gemeinschaften*) were breeding grounds for social relations based on deep emotional, quasifamilial commitments. Emile Durkheim (1893) referred to the solidarity characteristic of this kind of society as 'mechanical,' implying thereby that it had a certain automatic quality. Mechanical solidarity rests on a set of common values, internalized norms, and beliefs (a *conscience collective*) engendered by physical co-presence, a common focus of attention, and a sense of mutual awareness. This kind of solidarity is often expressed in a religious credo (Durkheim, 1912).

Mechanical solidarity appeared to be threatened, however, by the rise of industry and the expansion of market economies in Western Europe, North America, Australasia, and Japan beginning in the late eighteenth century. Among their many other effects, these transformations increased the size and scope of social networks, thereby affording many individuals greater options, ranging from marriage partners to occupations, in their daily lives. The growth of individualism and the concomitant decline of a *conscience collective* was the inevitable result (Simmel, 1922). It was far from evident how groups, communities, and societies could maintain mechanical solidarity in the wake of a burgeoning division of labor and its by-product, that is increasing individualism. Durkheim, the foremost early theorist of solidarity, initially argued that social order in industrial societies was not threatened by the division of labor; on the contrary, individuals in industrial society were held together by their mutual interdependence, a form of solidarity that he termed 'organic.' At the end of his life, however, he came to regard common values and norms (which he sometimes referred to as "the non-contractual basis of contract") as the basis for solidarity in all kinds of groups and societies (Durkheim, 1912).

Durkheim's insistence that solidarity requires compliance to a set of collective obligations based on particular values and norms has greatly influenced subsequent research. For example, a religious group is solidary only to the degree that its adherents comply fully with its obligations, both sacred (rites) and secular (tithing). Likewise, a working class is solidary only to the degree that individual workers regard themselves as members of a collectivity with its own obligations and refrain from engaging in activities such as strikebreaking that compromise or countermand these obligations.

Yet compliance to collective obligations can owe to both pecuniary and nonpecuniary causes. Consider the mobilization of labor in a profit-making firm. To attain maximum profit, firms demand that their employees perform to the best of their ability and refrain from shirking. Employees usually comply

with the firm's obligations not out of a sense of group solidarity but because they are individually compensated for doing so by receiving wages or salaries. In contrast, the members of a religious group or a working class are not given pecuniary compensation to comply with their corporate obligations. Hence, compliance in such groups must be due to other mechanisms.

Theoretical perspectives on solidarity may usefully be divided into three distinct types: *normative* perspectives suggest that solidarity arises from common values and norms, *structural* perspectives argue that it arises from common material interests, and *rational choice* perspectives hold that it arises from mutual interdependence.

The Normative Perspective

Normative theorists claim that solidarity is unlikely to result merely from the interaction of rational, self-regarding individuals (Parsons, 1951). This is because it is never in the interest of self-regarding individuals to adhere to collective obligations if they can profit by ignoring them. In a world of self-regarding agents, the only means of assuring the requisite compliance is by sanctioning. Normative theorists, however, hold that sanctioning is both too costly and unreliable to serve as a means of assuring high levels of compliance, especially among large numbers of individuals. In some cases, sanctioning breeds resistance. For normative theorists, the solution lies in values and internalized norms. These make individuals fit for social life by removing the conflict between the individual's interest and that of the relevant collectivity. If individuals willingly adhere to the values and norms that underlie corporate obligations, then they will act to promote collective ends without the need for carrots and sticks. According to normative theorists, socialization is the key to the attainment of solidarity. Solidarity therefore is most likely to emerge in socially homogeneous collectivities. It should be noted that the emergence of values and norms is exogenous to the theory, as are socialization processes. Moreover, although casual observation confirms that compliance with values and norms is never automatic, normative theory has little to say about the conditions under which the requisite compliance is likely to occur.

The Structural Perspective

Structural theorists typically, if implicitly, regard solidarity as an outcome of individually self-regarding action. In their view, individuals form solidary collectivities principally by virtue of sharing common (often material) interests. They discover that they share interests in the course of mutual interaction, and especially when they perceive themselves to be threatened by powerful antagonists (Marx, 1978 [1845–46], p. 179; Coser, 1956; Collins and Sanderson, 2009). When mutual interaction occurs repeatedly, this may set the stage for the development of sentiments, or affective feelings, that further strengthen compliance to collective obligations. However, the weaknesses of structural theories of solidarity are notable. Both commonality of interest and repeated interaction are insufficient causes of solidarity. To see why, note that solidarity varies widely among workers and married couples. Sometimes workers refuse to support striking colleagues, and the incidence of divorce has risen dramatically in nearly all industrial societies. Neither of these trends is easily accounted for by the explanatory apparatus of structural theories. Furthermore, if the individuals who share interests are self-regarding, as most structural theorists contend, then why would they ever join forces to pursue their common ends (a point that was already made by Parsons in 1937)?

The Rational Choice Perspective

This question is the point of departure for rational choice perspectives of solidarity, which attempt to reconcile sociological and economic perspectives. Truly self-regarding actors will *not* join a group to pursue common ends when, without participating, they can reap the benefit of other people's activity in obtaining them. Instead of contributing to the common weal, rational actors will free ride (Buchanan 1965; Olson, 1965) and behave opportunistically when it is expedient. The upshot is minimal solidarity despite an extensive commonality of interest. The rational choice theory of solidarity (Hechter, 1987) hinges on the group's capacity to preclude free riding.

In this theory, rational individuals form groups to obtain goods that they either cannot produce on their own or cannot attain as economically. The ultimate motivation for group formation is held to be the individual's desire to gain access to jointly produced goods. These goods can only be produced if prospective members comply with the rules and obligations that are necessary to ensure production of the given joint goods. The more dependent individuals are on the group for access to valued goods, the greater is its potential power over them. This dependence increases when the given goods are not readily available elsewhere, when members lack information about alternatives, when the costs of leaving the group are high, and when personal ties to other members are strong. Moreover, the greater the dependence of members on a group, the greater their willingness to comply with highly extensive obligations. Hence, dependence creates conditions not just for the emergence of corporate obligations, but for obligations that guide and regulate behavior to a high degree.

Yet dependence is an insufficient cause of compliance. Children tend to be highly dependent on their parents, but this is no guarantee that they will routinely perform their chores or study diligently in school. Dependence by itself is unlikely to resolve the free rider problem. Free riding can only be precluded when the given group has a high control capacity. This control capacity, in turn, is a function of monitoring and sanctioning. Monitoring is the process of detecting noncompliance to corporate obligations; sanctioning is the use of rewards and punishments to induce compliance. The theory therefore holds that compliance to corporate obligations – an indirect measure of solidarity in noncompensatory groups – is jointly a function of dependence and control mechanisms. That said, this theory remains incomplete because the sources of individual dependence are exogenous to it.

Since it can be attained as a result of compensation as well as normative obligation, the study of solidarity poses serious challenges to empirical researchers.

After a long period of dormancy, interest in solidarity has increased in several social science disciplines. The rational choice theory of solidarity has been used to explain variations in legislative party voting (Hechter, 1987), the membership rules of friendly societies and mutual benefit associations (Hechter, 1987), the survival of US intentional communities (Hall, 1988), cross-national crime rates (Hechter and Kanazawa, 1993), social order in Japan and the United States (Miller and Kanazawa, 2000), the prevalence of nationalism in history (Hechter, 2000), the survival of religions demanding high sacrifice from their adherents (Iannaconne, 1994; McBride, 2007), the causes of suicide bombing (Berman and Laitin, 2008), and the survival of individuals in prisoner of war camps during the American Civil War (Costa and Kahn, 2008). Whether group solidarity incites or inhibits intergroup conflict is now the subject of debate (Bhavnani and Backer, 2000; Fearon and Laitin, 1996; Gould, 1999). Legal theorists (Ellickson, 1991; Posner, 2000) have explored group solidarity as an institutional alternative to law as a means of dispute resolution. A variety of mathematical models of solidarity have been proposed by social and physical scientists (Doreian and Fararo, 1998). Finally, social psychologists have recently found that solidarity is more likely to develop among individuals who are engaged in intergroup conflict (Benard, 2012), on the one hand, and generalized as against reciprocal exchange networks, on the other (Willer et al., 2012).

Whereas the rational choice theory of solidarity emphasizes individual compliance with collective obligations, group solidarity evidently also entails the emergence of collective sentiments. The pioneering rational choice sociologist James Coleman (1990) argued that positive sanctions produced within groups may yield zealotry among some members. Other writers have sought to downplay the self-regarding behavioral assumptions of rational choice theory by stressing the role that emotions play in generating these sentiments of solidarity. On this view, Collins (2004) suggests that solidary groups are held together not so much by common interests as by positive emotional energy generated in the course of ritual interaction (Collins, 2004); this emotional energy is held to arise to the degree that people share a clarity of expectations (Turner, 2007). For Lawler et al. (2009), however, people form affective ties to groups if and when they attribute their individual feelings to membership in a group. They suggest that emotional energy derives not from ritual interaction, but from affiliation with given groups. Although an emphasis on the emotional basis of group solidarity is often regarded as an alternative to the instrumentalism of rational choice theory, it is unclear why positive emotional energy, whatever its source, cannot be modeled as a part – even quite an important part – of an individual's utility argument.

The empirical study of solidarity has been hamstrung by a lack of agreement on definitions of the concept. Defining solidarity as an intersubjective state (as normative theorists have typically done) posed a severe challenge for empirical research because there were no consensually accepted measures of individual values and internalized norms in social science. Direct measures of the sentiments or feelings that may hold within collectivities perforce were hard to come by.

Future Research

Future research on solidarity is likely to proceed along both methodological and substantive fronts. Methodologically, new measurement instruments have been developed that make it possible to gauge solidarity directly as an intersubjective state, rather than merely using behavioral compliance as a proxy. From Buchanan (1965) and Olson (1965) onward, rational choice models of solidarity have assumed that agents are purely self-regarding. Recent research findings challenge the adequacy of this assumption. For example, experimental games have been deployed in order to elicit variable individual motivations to contribute to public goods (Fehr and Gintis, 2007). These studies have demonstrated that individual motives, as revealed by strategies employed in playing public goods games, are mixed. Whereas some subjects indeed do consistently exhibit self-regarding motives, others seem to be more akin to the pro-social agents that are celebrated in classical sociological theory.

Substantively, there is much to learn about the interaction of solidary groups in wider social systems. Evidently, individual motivations are strongly affected by social contexts. Thus to the degree that small-scale societies engage in cooperative production, for example, self-regarding motivations are attenuated (Henrich et al., 2004). Likewise, individual participants in groups that employ generalized exchange identify with their groups – and appear to be more other-regarding – than members of groups that rely exclusively on direct exchange (Willer et al., 2012).

Since solidarity is built around a set of normative obligations and enforcement mechanisms, it follows that the normative content of any given solidary group may be more or less congruent with that of its global social environment. Thus, minority ethnic groups often espouse norms at variance with their host society. Adolescent peer groups evolve norms that are mutually inconsistent and generally inconsistent with school norms. Factory workers can embrace output restriction norms that are at variance with their employers' expectations, and inner city gangs and organized crime groups establish norms that are at variance with those of the society at large. The effects of solidarity in such countercultural groups are a matter of dispute among both social scientists and political decision makers (*see* Social Capital). Further research is needed to clarify the mechanisms that are responsible for the emergence of such countercultural groups and the consequences these groups have for the attainment of social order.

Along with sustained economic growth, solidarity is one of the two principal desiderata of polities and their rulers, not to speak of less encompassing collectivities. Typically, these two goals are considered to be mutually inconsistent: the policies that promote one ostensibly do so at the expense of the other. No doubt, this inconsistency has led economists and sociologists to focus their attention on different kinds of outcomes. This article suggests that much can be gained about the causes of solidarity, as well as economic growth, by combining the insights of each of these disciplines.

Abstract

Somatoform disorders, or somatic symptom disorder, as it is denominated in *Diagnostic and Statistical Manual of Mental Disorders*, fifth edition, are a heterogeneous group of mental health problems that are characterized by enduring bodily complaints and symptoms that are not due to organic dysfunction or disease. These patients perceive a wide range of severe symptoms like pain, gastrointestinal, cardiovascular, sexual, and/or pseudoneurological symptoms, which cause permanent attention, worry, and distress. They excessively seek medical help and reassurance, but have difficulties accepting the non-pathological results in medical examinations. The concept of psychological and psychosocial influences and causes is rejected, and mental health services are usually not attended. Biological, psychological, and psychosocial factors interact as precipitating, triggering, and maintaining factors of psychopathology. The different subtypes (somatization, conversion, pain disorders, hypochondriasis, and dysmorphophobia) are described with their central features: clinical presentation, epidemiology, comorbidity, and course. Current etiological and pathogenic models are introduced as a clinical and theoretical basis for therapeutic interventions. Besides general psychotherapeutic principles more specific interventions addressing the modification of subjective health-beliefs, illness behaviors, and coping skills are described. The clinical significance of somatoform disorders stresses the need for training programs to provide and improve basic diagnostic and therapeutic skills, especially in primary care. Future directions for the management of these disorders are outlined.

Introduction

The history of somatization phenomena, the 'borderland between medicine and psychiatry' (Lipowski, 1988), or in terms of neuroscience the problem of the 'body–brain-interface' (Guggenheim, 2000), can be traced back to ancient Greek medicine. Here the term 'hysteria' was used to describe patients' somatic complaints without the presence of somatic disease. Hysteria (from hystera = womb) was understood as a psychological problem in women, whose intrapsychic conflicts, resulting from the unfulfilled wish to bear a child, lead to somatic complaints (*see* Hysteria: History and Critiques). Similar clinical observations by different European clinicians since the mid-nineteenth century (Briquet, Charcot, Janet, Breuer) were antecedents of the Freudian concept of conversion disorder. The psychodynamic etiology and psychoanalytic treatment approach to patients with conversion disorders, 'functional' or psychosomatic complaints, and hysteria was most influential to the 1970s. Since 1980 the term somatoform disorders had replaced the traditionally used, but not precisely defined above mentioned terms of hysteria, that were mainly confounded with etiological (psychoanalytical) assumptions. Currently in *Diagnostic and Statistical Manual of Mental Disorders* (fifth edition) (*DSM-V*; APA, 2013) the term was changed into 'somatic symptom disorder'. The concept of somatoform disorders encompasses a heterogeneous group of psychiatric disorders that are characterized by three core features: (1) patients suffer from enduring or recurrent bodily complaints, symptoms and/or pain (e.g., palpitations, headache, fatigue, and dizziness), which are experienced as indicators of somatic illness, (2) psychological and social factors – usually refused as major influencing factors by the patients – play a predominant role in the development and course of these disorders, and (3) patients experience a general preoccupation with bodily symptoms and health concerns. In *DSM-IV* and the tenth edition of *International Classification of Diseases* (ICD-10) the requirement, that somatic symptoms must be 'medically unexplained' was a central diagnostic prerequisite, which is eliminated in the current DSM version.

This article describes the various subtypes of somatoform disorders, their prevalence, and etiology. Critical aspects regarding diagnosis, treatment, and management of somatoform disorders in healthcare systems will be discussed.

Classification and Epidemiology

From a nosological perspective, somatoform disorders were grouped together in *DSM-III* in 1980 for the first time. However, this clustering was primarily based on clinical criteria and not on empirically derived or laboratory findings. The *ICD-10* includes most of the somatoform disorders of the *DSM-IV* (American Psychiatric Association, 1994), except for conversion disorders that are grouped with the dissociative disorders. The main feature of these disorders is the "repeated presentation of physical symptoms with persistent request for medical investigations, in spite of repeated negative findings and reassurances by doctors that these symptoms are not primarily due to somatic illness. If somatic disorders are present, they do not explain the nature and the extent of the symptoms or the distress and preoccupations of the patient" (WHO, 1991). For the diagnosis of all somatoform disorders the patients' symptoms have to be of sufficient severity to warrant clinical attention. The *ICD-10* differentiates between four main nosological entities (seven different diagnoses) which were characterized by different diagnostic criteria (see **Table 1**). Recurrent, multiple somatic complaints that are not associated with any physical disorder are the essential feature of somatization disorder. The diagnosis requires a history of many bodily symptoms of several years' duration with onset

 http://dx.doi.org/10.1016/B978-0-08-097086-8.27069-4

Table 1 Somatoform disorders and their characteristics

Subtypes	*Characteristics and (selected) main criteria (*ICD-10*)*
Somatization disorder	● A history of at least 2 years of multiple and variable complaints which cannot be better explained by somatic factors or other psychiatric disorders (A) ● Preoccupation with the symptoms causes persistent distress and leads to seek repeated medical consultations (B) ● Persistent refusal to accept medical reassurance that there is no adequate physical cause (C) ● A total of six or more enduring autonomous symptoms from different groups (gastrointestinal, cardiovascular, genitourinary system, skin and pain symptoms) (D)
Hypochondriasis	● A persistent belief of the presence of a serious physical disease (A1) ● A persistent preoccupation with a presumed deformity or disfigurement (body dysmorphic disorder) (A2)
Somatoform autonomic dysfunction	● Symptoms of autonomic arousal attributed by the patient to a physical disorder (heart and cardiovascular system/upper and lower gastrointestinal tract/respiratory or genitourinary system) (A) ● Two or more autonomic symptoms like palpitations, sweating, dry mouth, flushing or blushing, epigastric discomfort etc. (B)
Persistent somatoform pain disorder	● Persistence of severe and distressing pain for at least 6 months which cannot be explained adequately by a physiological process or physical disorder (A)

before the age of 30. In somatoform autonomic dysfunctions symptoms of autonomic arousal (e.g., palpitations, sweating, and stomach discomfort) are the main complaints of the patients. Chronic pain syndromes (duration >6 months) like tension headache, lower back pain, and atypical facial pain are labeled as persistent somatoform pain disorder. Excessive and dispropriate thoughts, feelings, and behaviors can play either a major role within a general medical condition (e.g., rheumatoid arthritis) or may be the only determinants of pain (e.g., not otherwise specified lower back pain). The pain in one or more anatomical sites is the main focus of clinical presentation.

Conversion disorder is mostly a transient disturbance of physical functions (typically occurring in stressful situations) which do not conform to current concepts of the anatomy and physiology of the nervous system. Many disorders seem to be neurological disorders (e.g., motor disorders or disturbances of sensory function), but do not show the usual pathological signs. Hypochondriasis is not exclusively a secondary phenomenon within affective, anxiety, or psychotic disorders but a diagnostic subgroup of its own. Patients are preoccupied with their belief of already suffering from a severe illness or the fear of becoming ill with a life-threatening disease (e.g., cancer, stroke, or AIDS). The diagnostic congregation of body dysmorphic disorder – which is rarely seen as a full-blown syndrome – is different in the nosological systems. In the *ICD-10* it is a subgroup of hypochondriasis, with the preoccupation on a presumed deformity or body abnormality. Patients subjectively feel unattractive, ugly, and disfigured despite lacking evidence for major defects in appearance or stigmata. Positive feedback from significant others about normality in appearance has no corrective effects.

Somatoform disorders show high prevalence rates in the community, especially in the primary health care system. In industrialized societies up to 4–19% in the general population suffer from somatoform disorders (Hiller et al., 2006; Simon and von Korff, 1991). In medical outpatient and inpatient treatment, patients with the probable diagnosis of somatoform disorders are estimated at up to 25–30%. The onset is in adolescence or young adulthood, and the course in untreated cases is usually chronic with a waxing and waning of symptoms. Women, persons from lower social classes, and ethnic subgroups are more likely to develop somatoform disorder. Furthermore, somatization is more often seen after separation and divorce. Somatoform disorders are often associated with other psychiatric disorders, especially depression, anxiety disorders, substance abuse disorders, and personality disorders (*see* Depression; Anxiety and Anxiety Disorders; Personality Disorders). Patients with somatoform disorders are often not correctly recognized in primary care and therefore insufficiently treated. The latency between the onset of the disorder, the appropriate diagnosis, and the referral to adequate treatment is usually high. These factors lead to largely extended costs for medical and psychosocial services (14-fold costs of care than average costs of outpatients and sixfold costs in inpatients) (Barsky et al., 2005).

Etiology and Course

No single factor can explain the pathogenesis of somatoform disorders. Comparable with other psychiatric disorders, biological, psychological, and social factors interact in complex ways (*see* Mental Illness, Etiology of). Their impact probably varies over time within the same individual and between different patients resulting in a common final pathway. There is no general etiological model for somatization phenomena (Rief and Broadbent, 2007). However, interesting neurobiological studies demonstrate that patients with somatization disorder may have an abnormality in cortical and neuropsychological functioning, e.g., bifrontal impairment of the hemispheres, abnormal auditory-evoked potentials, and abnormal levels of cortisol (Rief et al., 2010; Tak and Rosmalen, 2010). Several etiological conditions play a prominent role, especially in maintaining the process and can be considered as empirically derived risk factors (see **Figure 1**).

1. Genetic risks, e.g., higher rates of somatoform disorders for monozygot than for dizygot twins, and in first-degree relatives.
2. Higher physiological reactivity which can lead to pervasive interoception of physiological signs. Unspecific bodily

Figure 1 Risk model for somatoform disorders. Adapted from Rief, W., Hiller, W., 1998. Somatisierungsstörung und Hypochondrie (Somatization Disorder amd Hypochondriasis). Hogrefe, Göttingen.

sensations are perceived and interpreted as symptoms of disease. The consequence is the intensification of the complaints and elevated attention to them.

3. Biographic vulnerability, a high proportion of physical, sexual abuse (within the family), and traumatic experiences like war and natural catastrophes are overrepresented in these patients. Furthermore, chronically ill parents or siblings, and learning by model within the family may influence the localization and types of somatoform symptoms.
4. Personality traits, e.g., difficulties in the perception and expression of emotions (alexithymia) with an inverse relationship of reduced emotional expressions and heightened psychophysiological arousal in stressful situations.
5. Unrealistic health beliefs with a low tolerance for normal complaints, 'catastrophizing' ideas about physiological processes, and exaggerated expectations regarding effects of modern medicine to all kinds of complaints.
6. Chronification factors like multiple diagnostic procedures, the overvaluation of normal variants through the caring physician (iatrogen factors) and positive (e.g., attention from others) or negative reinforcement (e.g., defense mechanism for negative emotions, advantages of the sick-role, withdrawal from responsibilities).

Which of these potential factors are important, and how much impact they have in the individual patient have to be determined within the diagnostic and psychotherapeutic process (*see* Mental Illness, Etiology of).

Diagnostic Process

The diagnostic process follows a sequence starting with a careful monitoring of all presented bodily complaints and ending up with a reliable and valid diagnosis of a specific subtype of somatoform disorder and its severity (Schaefert et al., 2012). The knowledge of base rates for somatoform disorders and potential severe medical disorders which have to be ruled out, age of the patients, and their presentation style, history of other bodily complaints and excessive visits to other doctors might be hints for the assumption of the diagnosis.

The physician is confronted with the dilemma of possible false decisions: (1) they might diagnose somatoform disorder although the symptoms are better explained by a somatic disease which has to be treated by medical guidelines (type-1 error, 'false positive'). As a consequence patients might not receive appropriate medical treatment and might feel stigmatized as mentally ill. (2) The diagnosis of a somatic disease/dysfunction is assumed although the patient suffers from a somatoform disorder (type-2 error; 'false negative'). In most cases doctors and patients judge the risk of missing the correct

somatic diagnosis as more adverse and therefore try to minimize it. However, this can be one of the major factors maintaining somatoform disorders. A pragmatic rule for diagnosis is "to have somatic diagnostic efforts as much as necessary but as less as possible." Thorough, but not excessive or indefinite, medical examinations have to rule our severe and harmful organic disease and dysfunctions that might be causing the symptoms (e.g., hyperparathyroidism, multiple sclerosis, or brain tumor). It has to be supported by adequate and plausible procedures (e.g., physical and neurological examination, laboratory examination). Results and documents from other doctors should be revised in order to prevent repeated examination without relevance. A precise mental health examination for a complete overview of previous severe psychiatric disorders and minor complaints and the current psychopathological status is necessary. In single cases it can be difficult to decide whether the symptoms can better be explained by affective, anxiety, and personality disorders or whether they are real comorbid states. The probability of comorbid diagnoses positively correlates with symptom severity of somatoform disorders. The sequence over time and the severity of symptoms are helpful in finding the correct hierarchy. Symptoms, pathological illness behavior, course, and consequence of the complaints will allow one to find the adequate nosological diagnoses along with the operationalized diagnostic criteria. This diagnosis within the group of somatoform disorder has the status of a working hypothesis and is needed for concrete treatment planning. If the patient visits a mental health specialist he or she will gather specific information regarding nosological diagnosis. A sophisticated analysis of all relevant information concerning the individual development, learning, and predisposing factors, the onset, and further course of the symptoms, which is based on a life-chart interview, and information about actual psychosocial conditions, conflicts, and traumata is inevitable. Of course it partly depends on the theoretical assumptions and etiological models of the different psychotherapeutic schools (*see* Differential Diagnosis in Psychiatry).

Treatment

Because psychological factors are most influential in the development and course of somatoform disorders they have to be addressed in every effective treatment. Of course the setting, intensity, and content of psychological interventions can vary depending on factors like severity of symptoms (duration, intensity, functional impairments), comorbidity, insight, and motivation of the patient and availability of psychotherapy. In a step-by-step approach the primary care physician should start with short-term verbal interventions. Acute and isolated somatoform symptoms may respond to psychoeducation and counseling within the usual medical visits. Counseling and advice for general and easy-to-administer methods of symptom monitoring and management can be helpful. The physician should know the pitfalls in the treatment of patients with somatoform disorders and avoid procedures, which might reinforce the patients' pathological illness behaviors (e.g., no medical tests or laboratory examinations without clear indication). Information about and motivation for more specific forms of psychotherapy are essential if these basic interventions within the primary care system are not sufficient. For the more severe patients a referral to mental health experts is needed, for chronic and therapy-refractory cases even psychiatric or psychosomatic inpatient treatment may be necessary. Unspecific factors, which are important in any psychotherapy (e.g., therapeutic alliance, expectations of being helped, enhancing the sense of mastery, etc.) can be differentiated from specific therapeutic techniques and be adapted to relevant pathological processes in somatoform disorders (see below). Multimodal and multidisciplinary treatment approaches seem to be more effective than single treatment approaches (Mayou et al., 1995).

A validating, accepting, and (especially in the beginning) nonconfronting patient–therapist relationship is a prerequisite for active participation in therapy. It is also the basis for the development of an alternative, holistic model of illness, the motivation to change, and active participation in therapy. Self-monitoring diaries aim at a precise identification of symptoms in relation to external or interoceptive stimuli, events, and their positive and negative consequences in concrete situations. Psychoeducation and cognitive therapy are essential for a critical discussion and revision of inadequate concepts about health and disease and a better understanding of ongoing mechanisms. For example, the hypochondriac patient may realize the effects of a feedback loop leading to a vicious circle as is the case in increased autonomic arousal through anxious thoughts and worries about illness. In a collaborative way the therapist tries to convey a more realistic and helpful paradigm of body–mind interactions which aims at a better understanding and mastery of symptoms. Relaxation training, breathing exercises, or mindfulness-based interventions are introduced as methods for an active reduction of tension, arousal, and apprehension. The patient is motivated to reduce maladaptive illness behaviors like body scanning and checking, excessive medical visits, seeking reassurance, and social withdrawal. Cooperation with physicians and family members is warranted so that they can avoid inadequate reactions to the patients' illness behaviors. Alternative behaviors, e.g., exercises, sports, and positive activities have to replace the symptomatic ones and can help to re-experience bodily functions in a more positive way. Stress management, social competence, and problem-solving interventions can be used optionally to improve coping with stress, conflicts, and interpersonal problems. Furthermore, therapy has to prevent relapses and enhance a more balanced life style. As some of the symptoms might resist the described interventions or take a longer time to be effective, patients have to learn how to 'live with the residual complaints as best as possible' and to regain a better quality of life instead of waiting for complete remission.

Up to now there is no empirically validated form of specific pharmacological therapy. Clinical experience shows that in some cases tricyclic antidepressants and selective-serotonin-inhibitors might be helpful, especially in patients with comorbid depression, anxiety disorders, and pain. However, without concomitant psychotherapy the risk of relapse is usually high. Benzodiazepines and low-potency neuroleptics should not be given because of the risks of long-term intake, especially abuse and dependency in benzodiazepines and tardive dyskinesia in neuroleptics.

Compared to other psychiatric disorders the empirical evidence for effective treatments is still low in somatoform disorders. But there is a growing number of controlled outcome studies since the syndromes were clearly defined in 1980. These studies have to face the fact that most of these patients are not treated within mental health services but in the primary care system or in consultation and liaison services. Additional difficulties arise from the complexity of recent approaches, which can only be evaluated as 'total treatment packages' (*see* Antidepressant Drugs; Behavior Therapy: Psychiatric Aspects).

Summary and Outlook

The clearer operationalization of diagnoses within *DSM* and *ICD* classification systems stimulated a lot of empirical studies concerning the epidemiology, etiology, pathogenesis, and treatment of somatoform disorders in the last three decades. Medical and mental health services have realized the clinical relevance of these disorders and the need for early recognition, collaborative, stepped-care, and multidisciplinary intervention programs (Schaefert et al., 2012). Clinical observations and outcome studies have challenged the former statement, that patients with somatoform disorders in general have a poor prognosis. The acceptance of empirically based psychotherapeutic and psychiatric interventions can be enhanced if their positive effects are transparent to the patient. Convincing models for a better explanation and understanding of symptoms, the definition of limited and concrete treatment goals, and the provision of successful experiences in symptom reduction and improving coping abilities may have the function of a 'positive vicious circle' and convey a sense of mastery.

However, patients and their caregivers have to overcome a series of obstacles:

1. The first step is the correct recognition and early diagnosis by the primary care physician.
2. Divergent health belief systems of patient and physician may burden the relationship and cooperation between them, so that it is difficult to realize psychological interventions.
3. Although psychological treatment is indicated, physicians often avoid time-consuming verbal interventions or are not adequately trained for their application. However, it is not clear whether psychotherapeutic interventions, which are proven within a psychotherapeutic context, can be adopted to primary care without diminishing their efficacy.
4. If physicians try to refer to mental health experts a lot of patients refuse this referral (e.g., for reasons of stigma) or are not motivated for psychotherapy. Since empirical validation of treatment approaches for subtypes of somatoform disorders is still different, the selection of therapeutic methods often depends on local availability and personal preferences rather than on evidence-based criteria.

Each of these items is a challenge for clinical and research efforts as well as for a better dissemination of existing knowledge and competence to different health professionals who are involved in the treatment of somatoform patients. Since the first edition of this text a lot of empirical studies have contributed to our knowledge and are congregated in some *meta*-analyses and Cochrane reviews.

In the last decade a controversial debate concerning the nosological congregation in somatoform, related disorders and their diagnostic criteria (Rief and Hiller, 1999) was ongoing. Since the introduction of the modified concept of 'somatic symptom disorder' in *DSM-V* it is even more pronounced. Especially the elimination of the requirement that symptoms must be 'medically unexplained' is criticized. Prominent researchers call the *DSM-V* concept as poorly tested and as too 'loose'. In the case of 'false positive diagnosis' the patient has to bear the burden of severe or harmful consequences, especially if underlying medical causes are missed and not treated adequately. Additionally many patients maybe 'mislabeled as mentally ill' (Frances, 2013). High rates of mutual comorbidity between anxiety, affective, substance abuse, and somatoform disorders have challenged the usefulness of the concept of discrete and stable nosological entities and different treatment needs. Some clinicians had proposed a concept of spectrum disorders with more transient borderlines between different, but obviously linked, clusters of psychopathology and their courses in a long-term perspective. Specifically the relevance of subclinical forms of disorders as precursors and remaining psychopathological states after partial remission is stressed. Some recent candidates are thought to be potentially affiliated as psychiatric diseases with apparent parallels to somatoform disorders. Chronic fatigue syndrome, fibromyalgia, and multiple chemistry sensitivity, etc. are syndromes with bodily complaints of unknown etiology and pathogenesis. Their treatment might profit from adopting interventions, which have been successfully applied in somatoform disorders.

Abstract

The history of somatotherapy is as old as the identification of mental health problems, since ancient times. However, the modern history spans the past century. The history of somatotherapy for mental illness is also a reflection of the understanding of mental illnesses during those periods. This article traces the history from chemical substances to control aggressive behaviors (not modern psychopharmacological agents), to fever therapy and insulin coma treatments. On a parallel was the development of methods to induce seizures by chemical and electrical methods – electroconvulsive therapy – and by other methods of brain stimulation – repetitive transcranial magnetic stimulation, deep brain stimulations, and transcranial direct current stimulations. The future may see stereotactic surgeries and other methods of intracranial localized brain stimulations. Other physical methods of treatments, like vagus nerve stimulation, phototherapy, sleep-inducing therapies, and sleep deprivation therapies, had shorter lives.

Somatotherapy refers to the treatment of psychiatric disorders by physical, chemical, or surgical means. Ancient methods included the use of blood letting, blood-sucking leech bites, branding, cold packs, straight jackets, and many more rather cruel, traumatic and not-very-safe methods. The development of modern somatotherapy began in the nineteenth century with the introduction of morphine, bromides, and chloral hydrate for sedation and control of behavioral abnormalities. It continued in the first quarter of the twentieth century with the introduction of malaria-induced fever for syphilitic general paralysis, and prolonged sleep. It was during the 1930s that insulin coma therapy (ICT), electroconvulsive therapy (ECT), and psychosurgery were introduced. ICT and ECT were the first effective physical therapies for schizophrenia without considerable risk. It was during the 1940s that the first causal treatments in psychiatry, penicillin for syphilitic general paralysis and nicotinic acid for cerebral pellagra, were introduced. Introduction of therapeutically effective psychotropic drugs began with the introduction of lithium in 1949. By the year 2000, well over 20 neuroleptics, antidepressants, and anxiolytics were in clinical use. There are also three mood stabilizers for bipolar disease, and a couple of cholinesterase inhibitors for Alzheimer-type senile dementia. Introduction of the spectrophotofluorometer in the 1950s led to the development of neuropsychopharmacology. The development of receptor binding assays in the 1970s, followed by the separation of receptor subtypes in the 1980s and the introduction of a new genetic

Developments that led to pharmacotherapy

1806	Morphine	Serturner of Germany isolated morphine from opium	Morphine was used for controlling agitation and aggression.
1826	Bromine	Isolation by Balard in France	Bromine was separated from the ashes of the seaweed in France by Balard in 1826; potassium bromide was used for relieving restlessness and anxiety, and was introduced for clinical use in the late 1850s.
1832	Chloral hydrate	Chloral hydrate was synthesized in Germany by Liebig	Chloral hydrate was used for insomnia (Lehmann and Ban, 1970).
1880s	Hyoscine		Subcutaneously administered combinations of morphine (or apomorphine) and scopolamine (hyoscine) became the prevailing treatment modality of excitement and agitation in psychiatry by the dawn of the twentieth century (Ban, 1969).
1864	Barbiturates	Barbituric acid was synthesized by von Baeyer	The synthesis of malonylurea (barbituric acid) opened the path for the development of barbital (veronal), the first barbiturate hypnotic introduced in 1903. Barbital, together with many other long-, intermediate-, short-, and ultrashort-acting barbiturates, dominated the treatment of insomnia for about 50 years (Lehmann, 1993).
1930s	Inhalation of 30% carbon dioxide and 70% oxygen mixture		One of the targets was catatonic inhibition, which by the mid-1930s had been transiently removed in some patients by the inhalation of a 30% carbon dioxide and 70% oxygen mixture, and the administration of sodium amobarbital and apomorphine (Loevenhart et al., 1929).

Beyond behavioral control			
Mid-1890s	Fever therapy	Wagner-Jauregg (he received the Nobel Prize in 1927 for introducing the first effective treatment of neurosyphilis)	Wagner-Jauregg's fever therapy was based on his clinical observations that his patients, recovered from psychosis on developing high-grade fever, based on which he induced fever with tuberculin vaccine in several of his patients with general paresis and found favorable results. He replaced the vaccine in 1917 by blood from patients with tertian malarial attacks, because malaria could be terminated by quinine. Six of the first nine patients treated with 'fever therapy' improved; three fully recovered (Wagner-Jauregg, 1919). Though tried in other psychiatric disorders (e.g., depression, schizophrenia) and fever had been induced by means, e.g., typhoid vaccine, killed *Escherichia coli* suspension, sodium nucleinate, sulfur in oil, and hot bath, even in general paresis, only in one-third of the patients did it yield 'satisfactory' results (Pichot, 1983).
1900	Sleep therapy	Macleod	First introduced in Shanghai with the employment of bromides ('bromide sleep') by Macleod for mania in 1900. After 1 year, Wolff employed methylsulfonal ('Trionalkur'). Epifaneo in 1915 reintroduced 'prolonged sleep' ('*l'ipnosiprolongata*') with long-acting barbiturates, later adopted by Klaesi for schizophrenia as 'continuous narcosis' (*Dauernarkose*) (Klaesi, 1922). During the 1930, the 1940s, and the 1950s, 'sleep therapy' was used in conditions ranging from manic and catatonic excitement, through severe anxiety and depression, to various forms of schizophrenia. Various combinations used frequently – Somnifen (diethyl- and allyl-isopropyl-barbituric acid) used by Klaesi, Cloetta mixture (paraldehyde, amylhydrate, chloral hydrate, alcohol, isopropyl-allyl-barbituric acid, digalene, and ephedrine). Sleep therapy was of marginal benefit, but of considerable risk; there was 5% fatality from pneumonia and/or circulatory collapse. Nevertheless, 'sleep therapy' was lingering on, even after the introduction of new psychotropics – with the incorporation of drugs like chlorpromazine in some of the 'sleep mixtures' – before fading away in the 1960s.
1971	Sleep deprivation	Pflug and Tolle	Sleep deprivation was found to be therapeutic in endogenous depression (Pflug and Tolle, 1971). Since the early 1970s, sleep deprivation has been employed with success in the facilitation of the therapeutic effect of these drugs.
1923	Insulin		The first report on the successful treatment of symptomatic depression with insulin in diabetic patients was published in 1923. Insulin was introduced into psychiatry for stimulation of appetite and sedation in the late 1920s. Manfred Sakel's report in 1930 was one of the first on the therapeutic effect of insulin in morphine withdrawal.
1940s	ICT	Sakel	Sakel established the effectiveness of ICT in schizophrenia. He published his findings in a series of 13 papers in the *Wiener Medizinische Wochenschrift* between November 1934 and February 1935 (Sakel, 1935). ICT fared favorably to all other therapies used in the treatment of schizophrenia in the 1940s. ICT was short-lived in the Western world. In the Soviet Union and China, it remained one of the major forms of treatment of schizophrenia until the late 1980s.

technology in the 1990s, rendered the tailoring of psychotropic drugs possible.

Psychosurgery

Since antiquity, humans tried to treat mental illnesses surgically. Trephination of skulls dates back to the stone ages. Skull trephinations have been described to be performed in the Mesolithic and Neolithic eras; the procedure seemed to have taken place intra vitam since the healing process was obvious. Trephination was performed for religious reasons, as part of the treatment of somatic and psychic disorders, for segregation purposes, and also as a punishment.

Skull surgery was used for treatment of affective disorders started with the works of Gottlieb Burckhardt (1837–1907) and Ludvig Puusepp (1875–1942), at the dawn of the nineteenth century.

John Fulton (1896–1960) extensively studied the function of the cingulate cortex in primates. In his works with Carlyle Jacobsen, he reported their experience with two higher primates, which were lobectomized and became remarkably flaccid, though maintaining their ability to perform tasks.

The Portuguese neurologist Egas Moniz (1874–1955) along with Almeida Lima (1903–1985) introduced 'frontal leucotomy' for psychiatric illness, treating a woman suffering from 'mélancolie anxieuse' with satisfactory results. Similarly, Freeman and Watts and Tooth and Newton, working independently, performed prefrontal lobotomies for treating patients with mental disorders. However, the initial enthusiasm for this innovative treatment of medically intractable psychiatric disorders and chronic pain was soon tempered by reports of significant undesirable side effects.

Neurosurgeons started looking for alternative surgical procedures that would increase safety without reducing efficacy. Among them were less invasive and relatively more selective procedures such as cingulotomy, thalamotomy, amygdalotomy, and other stereotactically guided lesioning procedures, which targeted specific brain structures without damaging adjacent brain areas (Brotis et al., 2009).

Electroshock Therapy

The notion that convulsions may promote wellness has existed for centuries. During the sixteenth century, the Swiss alchemist Paracelsus gave camphor by mouth to induce convulsions and 'cure lunacy,' following which several cases of convulsions induced by chemical means, specifically camphor in oil, were documented in the eighteenth and nineteenth centuries (Payne and Prudic, 2009).

In 1934, Ladislas Joseph von Meduna, a Hungarian neuropsychiatrist, conducted experiments in treating patients with schizophrenia by inducing repeated seizures. Meduna's own neuropathology studies found that the glial cell concentrations in the brains of patients with epilepsy were much higher than normal, whereas glial cell concentrations in the brains of patients with schizophrenia were much lower. Meduna thus hypothesized that seizures may be 'protective' against psychosis and that inducing convulsions in patients with schizophrenia could reduce their symptoms (Fink, 2004). He demonstrated a significant decrease in psychotic symptoms in patients treated with a series of induced seizures with dramatic improvement especially noted in patients who appeared to have catatonia (Fink, 1984).

Meduna began with intramuscular injections of camphor, which was known to be a stimulant at lower doses. However, since camphor was painful and variable in its effect, he switched agents to pentylenetetrazol (Metrazol), a more refined synthetic substance. Although this method was effective in promoting seizures, it was still variable in its effects and produced a sense of panic in patients (Mankad et al., 2010).

In 1938, Italian scientists Cerletti and Bini succeeded in defining the parameters necessary for applying electricity

Psychosurgery	
Frontal leucotomy	Introduced in 1937 by Portuguese neurologist Egas Moniz, assisted by neurosurgeon Almeida Lima for the treatment of schizophrenia
	Based on the fact that, by creating lesions in the prefrontal cortex, abnormal activity, presumably originating in this region, would be prevented from spreading to other areas of the brain, which could worsen the symptoms of the disease
	Classical lobotomy causing extensive brain injury fell into disuse after the 1950s, being replaced by localized procedures
Anterior cingulotomy	Currently the most popular psychosurgical procedure performed in the United States, earlier it was performed as an open procedure; results using stereotactic cingulotomy have recently been described
Stereotactic subcaudate tractotomy	Introduced in 1964. Radioactive yttrium drops are implanted in the tissue to be damaged, the substantia innominata, and beneath the head of the caudate nucleus
Limbic leucotomy	Introduced in 1973 by Kelly and Mitchell-Heggs; a combination of bilateral cingulotomy and subcaudate tractotomy
Anterior capsulotomy	Lesion to the anterior limb of the internal capsule, containing radiating anterior thalamic fibers connecting the cortex to the pons
Amygdaloidotomy	Clinical experience with stereotactic lesions of the amygdala has shown that amygdaloidotomy in a large percentage of cases resulted in a marked reduction in antisocial behavior (Soares et al., 2013)

directly to the human scalp; they treated a 39-year-old man who was found delusional in a train station. He recovered fully after 11 treatments without adverse effects and thus ECT was born.

Electroshock therapy (EST) was administered through electrodes placed on both temples that Bini found safe in dogs. Cerletti and Bini reported their findings with EST to the Italian Academy of Medicine in Rome on 28 May 1938. The treatment was therapeutically effective and safe; the only drawbacks it had were fractures and memory disturbance. The risk for memory disturbance with EST was greatly reduced by the use of 'brief-pulse currents' and moving the path of the current in the brain away from the memory centers by locating the electrodes on one side, or over the very front of the head. An added advantage of bifrontal electrode placement is that seizures are elicited at near-threshold frequencies.

The risk for fractures was greatly reduced by pretreatment with a neuromuscular blocker. Bennett in the United States was the first in 1940 to employ curare to relax the muscle. Curare, a substance that competes with acetylcholine at the neuromuscular junction, was replaced by succinylcholine, a safer drug, which prevents the action of acetylcholine by depolarizing the muscle end plates.

To prevent the panic that is caused by not being able to breathe, succinylcholine administration is preceded by the administration of a short-acting barbiturate. ECT, administered under general anesthesia with continuous oxygenation and monitoring of the body's physiology during treatment, is the safest among the somatic therapies today. It offers specific advantages for the elderly, in pregnancy, and for patients with cardiac disease.

From that time through the 1950s, ECT was extensively used in the United States where it joined a cadre of somatic therapies, including psychosurgery and ICT, that were being used to treat severely ill patients for a broad variety of symptoms. Other somatic treatments were introduced during this period, but ECT was the only treatment that flourished.

The indications of ECT have been extended over the years from schizophrenia to include mania and depression. However, in mania and schizophrenia, it is used only in treatment failures or in patients with specific contraindications to drugs. In depression, ECT is also used as primary treatment in delusional psychotic patients and in patients perceived to have suicidal risks.

In the mid-1990s, a new technique, high-energy transcranial magnetic stimulation (TMS) of the brain, was introduced. Expectations were high that it could eventually replace ECT. This, however, was not to be the case. Compared with ECT, the physiological effects of repetitive transcranial magnetic stimulation (rTMS) are rather modest (Payne and Prudic, 2009).

Transcranial Magnetic Stimulation

The first reports documenting activation of human brain by an electromagnetic field appeared as early as 1896. Jacques-Arsèned'Arsonval and, later, Sylvanus P. Thompson (1910) demonstrated that placing the head near an electric coil generating a time-varying magnetic field induced the sensation of phosphenes (i.e., the subjective sensation of light) and vertigo. Subsequent efforts were pursued aimed at refining the technique; however, all these magnetic stimulation devices were technically difficult to operate, prone to extreme overheating, and had no mechanisms to address the interference generated by the stimulating fields.

In the late 1970s and the early 1980s, Anthony Barker and collaborators at the University of Sheffield, UK, overcame many of these earlier technical problems and developed a device capable of generating peak magnetic fields as high as 2 T. This work served as a precursor to the development of a stable and reliable device and, ultimately, the first commercially available magnetic stimulator. During the past 20 years, the application of TMS in clinical neurology and neuroscience research has grown steadily due to improvements in coil design and the development of stimulators capable of rapid discharge rates, its combined use with other neuroimaging modalities, and a greater understanding of the technique (George et al., 1999).

rTMS is a noninvasive neurophysiologic method to induce electrical currents within the brain. This technique can be used to transiently disrupt the function of a targeted brain area, functionally map cortical areas, assess cortical excitability, and even modulate its level of activity when delivered as a repetitive train of pulses. TMS is being widely used to investigate complex aspects of human brain function, such as learning and cognition, as well as sensory and motor function. Furthermore, its potential as a novel therapeutic treatment is being actively pursued in a variety of neurological and neuropsychiatric disorders (Merabet and Pascual-Leone, 2009).

In 1993, Hoflich et al. were the first to use TMS as a therapeutic modality in an open trial of TMS for depression (Hoflich et al., 1993). The best clinical gains have been observed on the use of rTMS for the treatment of major depression. In addition, therapeutic efficacy has been noted in mania, negative symptoms of schizophrenia, and potential anticraving in substance dependence (Mishra et al., 2011).

Vagal Nerve Stimulation

The background for studying whether vagal nerve stimulation (VNS) might have antidepressant effects, culminating in the first implant for this indication in July 1998 at the Medical University of South Carolina in Charleston (Rush et al., 2000) was a decade after the first human epilepsy implant (Penry and Dean, 1990). These hints were (1) mood effects of VNS observed in patients with epilepsy, (2) evidence by positron emission tomography scans that VNS affects the metabolism of important limbic structures, (3) the role of anticonvulsant medications in mood disorders, and (4) neurochemical studies in both animals and humans revealing that VNS alters concentrations of monoamines within the central nervous system.

During the clinical trials of VNS for epilepsy, several investigators noted mood improvements in their patients. Although decreased seizure frequency likely accounted for some of these improvements, the clinical impression was that mood improvement went beyond those attributable to improved seizure control alone. For example, some patients with minimal or no improvement in seizure frequency also reported substantial improvements in mood. Improved quality of life was also seen, and without seizure frequency changes in some patients (George et al., 2000).

Deep Brain Stimulation

Electrocorticography was further developed by many of the giants of neurosurgery: Keen, Krause, Sherrington, and Penfield. However, it took another 80 years before the technology advanced to the point that one could consider implantation of stimulating electrodes with which a patient could walk around.

Horsley had performed cortical ablations of the pyramidal system for movement disorders in 1890. Meyers first tested lesions of the basal ganglia to alleviate movement disorders in 1939; however, because these were open procedures before the advent of the operating microscope, the morbidity was significant with a 12% risk of mortality. This changed with the development of the stereotactic frame by Spiegel and colleagues.

In 1947, although Horsley and Clarke had designed an earlier stereotactic frame for use in animals using surface landmarks, it was not very accurate due to variability between subjects. Spiegel et al. used pneumoencephalograms to determine Cartesian coordinates of structures around the ventricles. In their first article describing the apparatus, they reported using the device for psychosurgery, pain (including phantom limb pain), pallidotomy for abnormal movements, electrocoagulation of the Gasserian ganglion for trigeminal neuralgia, and withdrawal of fluid from cystic tumors. They went on to develop a stereotactic atlas of the human brain to guide surgery. With these new tools, surgery could be performed with less than 1% mortality. However, even with the development of multiple frames, atlases, and lesioning techniques, there were issues of inaccurate targeting with stereotaxis. True microelectrode recording with low-impedance semimicroelectrodes was pioneered by Able-Fessard in 1961. These tools, as well as computer modeling, allowed for the development of neurophysiologic atlases of the human brain (Schwalb and Hamani, 2008).

There was an explosion of stereotactic functional neurosurgery in the late 1950s. Cingulotomy, anterior capsulotomy, and subcaudate tractotomy were used for pain and psychiatric disease as an alternative to the ice pick frontal leukotomies performed by Walter Freeman. Pallidotomy and thalamotomy were used for Parkinson disease and dystonia. The stage was set for electrical stimulation for movement disorders and psychiatric disease with the development of the first totally implantable pacemaker by William Chardack and colleagues for the heart in 1960.

Surgery for psychiatric disease had been decreasing since the introduction of chlorpromazine in 1954, and it effectively came to a halt, at least in most centers in the United States, in 1977, based on the recommendations of the National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research (Kopell and Rezai, 2003).

Among the most promising new applications of deep brain stimulations (DBS) at present are psychiatric disorders. This field is clearly of great interest due to the epidemiology of these diseases, especially major depression out of which more than 35% are resistant to medications and ECT (Rush et al., 2006).

Phototherapy in Psychiatry

Phototherapy or light therapy in psychiatry is closely intertwined with the original description of the syndrome of seasonal affective disorder. Two decades ago, Rosenthal and colleagues described a series of patients with histories of recurrent depressions that developed in the fall or winter and spontaneously remitted during then following spring or summer (Golden et al., 2005). Light therapy has been most extensively applied to the syndrome of 'winter depression.' In winter, these patients complain of fatigue, hypersomnia, overeating, and feelings of sadness; in the spring, these symptoms typically remit spontaneously. Subsequent to the original study in 1980, over a 100 patients with winter depression or seasonal affective disorder have been treated with bright light (Lewy et al., 1982). The analysis of randomized controlled trials suggests that bright light treatment and dawn simulation for seasonal affective disorder and bright light for nonseasonal depression are efficacious, with effect sizes equivalent to those in most antidepressant pharmacotherapy trials (Golden et al., 2005).

Transcranial Direct Current Stimulation (tDCS)

Transcranial direct current stimulation (tDCS) is a noninvasive form of brain stimulation in which a relatively weak direct current is passed into the cerebral cortex through small scalp electrodes. This resulted in a modulation of cortical excitability and spontaneous neural activity, depending on the polarity of the stimulation. Because of its neuromodulatory effects, tDCS has been investigated as a treatment for neurological and psychiatric diseases (Kalu et al., 2012).

Attempts to explore the effects of tDCS on mood and depressive symptoms in humans have been made for several decades. Anodal stimulation was suggested to diminish depressive symptoms, while cathodal stimulation reduced manic symptoms. Unfortunately, these results were not replicated (Nitsche et al., 2008).

Some open-label studies and clinical observations reported positive effects of tDCS in depression. However, controlled trials failed to replicate these findings. These initial mixed findings, together with the development of psychotropic drugs, led to a decreased interest in tDCS as a treatment tool for major depression during the 1970s and the 1980s.

Methodological improvements and the promising results of rTMS in depression led to reevaluation of the therapeutic application of tDCS. Based on the hypothesis that the left dorsolateral prefrontal cortex is hypoactive in depression (Grimm et al., 2008), the common rationale of currently performed studies is to modify activity in the prefrontal cortex and reestablish the balance of left and right prefrontal cortex activation (Kalu et al., 2012).

Other physical therapies, used sparingly, and for very specific disorders are sleep deprivation therapy and aversive therapies used in behavioral medicine (most considered as a type of behavior therapy, rather than physical therapies).

Sorokin, Pitirim Alexandrovich (1889–1968)

Inna Ponomareva, Kuban State University, Krasnodar, Russia

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article deals with the biography and sociological heritage of an outstanding social scientist, Pitirim A. Sorokin, whose pioneering ideas on social behavior and motivation, social revolution and mass starvation, social stratification and mobility, sociocultural dynamics and fluctuations, and the crisis of modern culture and altruistic love reflected the problems exercising people's minds in the challenging twentieth century and indisputably shaped the mainstream Russian and American sociology of that time.

Biographical Facts

Russian–American sociologist Pitirim A. Sorokin was born in 1889 in the village of Turya located in the Vologda province in the rural north of Russia. His father was a craftsman and his mother was a peasant. Pitirim was only 3 years old when his mother died. After her death, his father took to drinking. Pitirim and his elder brother, Vasily, had to earn for their subsistence from their childhood (their youngest brother Prokopy lived with the family of a maternal aunt). Sorokin's childhood, spent among the Komi, was complicated, but enriched by a religious and moral background. Sorokin received his elementary education at a two-form school in the village of Gum, and later continued his education at the Khrenovo Teachers School. In 1906, he was arrested for revolutionary activities and jailed in Kineshma prison, where he spent 5 months (he lived through six imprisonments in Soviet Russia). In 1907, his thirst for knowledge led Sorokin to leave his native land, and he hitched a ride on a train to St Petersburg. In 1909, Sorokin joined the Department of Sociology at the Psycho-Neurological Institute, newly opened by EV de Roberty and MM Kovalevsky. However, he soon moved to the Law Faculty of St Petersburg University, where he specialized in law under the guidance of LI Petrazhitsky, whose ideas were later popularized by Sorokin among an English-speaking audience. As a student at the Law Faculty, Sorokin became interested in the problems of social behavior and after obtaining a first-hand experience in criminology during two more imprisonments he wrote his first monograph, *Prestuplenie i kara, podvig i nagrada* (Crime and Punishment, Heroic Service and Reward) (1914). Having graduated from St Petersburg University in 1914, Sorokin began his teaching career there. The period from 1914 to 1922 is characterized by Sorokin's aspiration to "combine intense academic work with gut-wrenching and dangerous political activities" (Johnston, 1998). He participated directly in the events of the Russian Revolution in 1917 that would be the turning point in Russian history, his opinions on which were being reflected in the columns he wrote for the political daily newspaper *Volya naroda* (The Will of the People) under the heading 'The notes of a sociologist.' Sorokin hailed the February Revolution for its overthrow of Czarism, but he criticized The October Revolution because of its radical programs and actions. He was a leading member of the Social Revolutionary Party and the Russian Constituent Assembly (he served as a secretary to its leader, Prime Minister Alexander Kerensky). Sorokin was imprisoned twice in 1918 for his anti-Bolshevist propaganda and vigorous ideological fight with Communist leaders such as Lenin and Trotsky (he was even condemned to death but finally was freed by Lenin's order). Two of Sorokin's brothers died at the time of the Revolution (one was executed and the other died in prison). Among these bleak events there was one festive occasion for Sorokin in 1917 – he was married to Dr Elena Baratynskaya, a cytologist-researcher, with whom he lived happily the whole of his life. In 1920, Sorokin founded the first Department of Sociology at Petrograd University. In 1922, he received the degree of doctor of sociology, the first in Russia's history, as a result of the public debate on his work *Sistema sotsiologii* (System of Sociology) (1920). However, after being arrested once again, in September 1922 Sorokin was exiled from Soviet Russia together with many other outstanding scientists and intellectuals. In 1923, after a short stay in Germany and Czechoslovakia, Sorokin was invited to USA to deliver a series of lectures on the Russian Revolution. First, Sorokin delivered a series of guest lectures at the Universities of Illinois and Wisconsin. From 1924 to 1930 he worked at the University of Minnesota. It was during the Minnesota years that Sorokin published many of his great works, which brought him to the forefront of American Sociology. Among these works were *The Sociology of Revolution* (1925), *Social Mobility* (1927), *and Contemporary Sociological Theories* (1928). From 1930 to 1959 Sorokin worked at the Harvard University. In 1930, he founded the first Harvard University Department of Sociology, which he headed until 1942 (in 1946 the department was reorganized by Talcott Parsons as the Department of Psychology and Social Relations). This period is characterized by a revision of his previous views, by the shift from behaviorism and empiricism to the problems of culture, spiritual life, altruism, and love. Sorokin's ideas finally took shape of his integral model, presented in the four-volume book *Social and Cultural Dynamics* (1937–41). In 1949, he established the Harvard Research Center in Creative Altruism, which he continued to direct until his full retirement in 1959. In 1965, Sorokin was elected the President of the American Sociological Association (http://www2.asanet.org/governance/sorokin.html). In 1968, following 2 years of serious illness, he died in his family house in Winchester, Massachusetts. His two sons, who were born soon after the Sorokin family settled in Massachusetts, became outstanding

American scientists. Peter P. Sorokin (born in 1931) is a physicist and coinventor of the dye laser. Sergei P. Sorokin (born in 1933) is a cytologist-researcher, professor at Harvard and Boston Universities, and a composer. They treasure in memory all the things connected with their father's life and try to preserve his great sociological legacy through the functioning of the Pitirim A. Sorokin Foundation established in 2011 in Winchester, Massachusetts (http://www.sorokinfoundation.org or http://www.cliffstreet.org; http://www.pitirimsorokin.org (in Russian)).

Major Works

Two periods of Pitirim Sorokin's scientific and creative work can be distinguished: the Russian period (until 1922) and the American period (1923–68). The key sociological issues investigated during his Russian period are social behavior and motivation, the positivistic system of sociology, and famine. The American period is characterized by the strong interest in revolution, social stratification and mobility, social and cultural dynamics, and altruistic love. However, despite his having explored such a diversity of social problems, Sorokin's sociological outlook is integralistic (Ponomareva, 2011).

The problem of social behavior and motivation is considered by Sorokin in his early work *Prestuplenie i kara, podvig i nagrada* (Crime and Punishment, Heroic Service and Reward) (1914). The book is written in the spirit of a neopositivistic and behavioristic synthesis. It represents a systematic work on criminology, but with a historical and sociological orientation. As a whole, the work is devoted to two interconnected problems: the problem of social behavior, revealing itself in acts, and the problem of social motivation, revealing itself in reactions to acts. For Sorokin, the aggregate of human behavior breaks down into a number of acts and reactions to them, correlating with each other as cause and effect. He singles out three main forms of acts and reactions: permitted legal acts, which refer to fulfilling one's rights and duties and correspond to standard demands, followed by proper reaction; forbidden unallowed acts, which contradict and violate the demands of proper behavior that are followed by punishment; recommended acts, representing desirable and voluntary actions, exceeding the necessary level of proper behavior, that are followed by reward. If proper behavior is accepted as a norm, forbidden and recommended behavior should be considered as a deviation from it. Forbidden acts in the form of crimes are deviations for the worse, and are followed by negative sanctions in the form of punishment. Recommended acts in the form of heroic deeds and services are deviations for the better, and are followed by positive sanctions in the form of rewards. Punishment and reward determine and transform the acts of human behavior.

The main work of Sorokin's Russian period of creativity is his *Sistema sotsiologii* (System of Sociology) (1920), dedicated to social analytics and written from the viewpoint of neopositivism. In *System of Sociology* he tries to define the subject and the boundaries of sociology. The subject of sociology is treated by Sorokin in the following manner: "Sociology studies the phenomena of human interactions, on the one hand, and the phenomena, which appear as a result of this process, on the other" (Sorokin, 2002). The structure of sociological knowledge includes theoretical and practical sociology. Theoretical sociology investigates the phenomena of human interaction from the perspective of their real state and includes three sections: social analytics, social mechanics, and social genetics. Social analytics studies the structure of social phenomena in their static condition. Its tasks are "defining society or social phenomena, describing its main features, analyzing the interaction process, formulating main social laws" (Sorokin, 1992a). Social mechanics (social physiology), which Sorokin considers the most important section of sociology, deals with the processes of human interaction and with the forces determining human behavior in conditions of social regrouping. It faces such tasks as the study of regularities, displayed in social phenomena; the decomposition of complex social phenomena into the simplest elements; the study of peculiar features of these elements and their effects on human behavior and social life; the classification of behavioral factors and the determination of individual or group behavior. Social genetics (social dynamics), representing the evolutionary theory of social life, studies historical tendencies and explains deviation from them in different epochs of human history and spheres of social interaction. Practical or applied sociology investigates the phenomena of interaction from the viewpoint of their proper state. It includes social policy and represents the discipline of scientific management of society. It is called on to help in the realization of rational social reforms and gives humankind the ability to manage social forces.

Having published two volumes of *System of Sociology*, Sorokin postponed the writing of the third volume in order to study famine, a phenomenon typical of revolutions and mass starvation. But many chapters of his book *Golod kak faktor* (Hunger as a Factor in Human Affairs) (1921) were mutilated and cut out by Soviet censors, and finally the whole edition was destroyed by the Soviet government. Later, after Sorokin's death, the book was translated by his wife Elena and published in the USA (Sorokin, 1975).

Among the first books published by Sorokin in English is *The Sociology of Revolution* (1925), analyzing the causes and features of revolutions and written "with great behavioristic inspiration" (Sogomonov 1992). Sorokin claims that there are three typical phases in the cycle of all great revolutions. The first – primary – phase is characterized by the joy of becoming free from the tyranny of the former regime and the expectation of promised reforms. This is the so-called 'prelude.' During this stage, the government is humane and gracious, its policy is gentle, indecisive, and often helpless. The second – destructive – phase, representing reaction, is characterized by the eradication of not only obsolete, but also viable institutions and values of society. This is the so-called 'flood.' During this stage, the government is merciless, tyrannical, and sometimes blood-thirsty. Its policy is destructive and violent. The third – constructive – phase is characterized by the efforts to create a new social and cultural regime, based, however, not only on new revolutionary ideals, but also on reanimated prerevolutionary institutions and values, temporarily destroyed during the second phase of revolution. The main causes of revolution are universal suppression of the basic instincts of the majority of population, the impossibility of satisfying them, and the disorganization of power and social control. Suppressed

instincts during the revolution include alimentary instinct, instinct of property, instinct of self-preservation, sexual instinct, instinct of freedom, and instinct of self-expression. Disorganization of power and social control is understood by Sorokin as the power base's ineffective resistance to the revolutionary rise of repressed masses and its incapacity to develop sufficient countermeasures against the pressure of repressed instincts, in order to reach a state of social balance and to redirect repressed impulses toward another, nonrevolutionary channel. The continuous suppression of instincts leads to the endless fatigue of the population, as a result of which the demand for boundless freedom is changed by the thirst for order. If society realizes that the only correct way of development is not through mortal hostility, but through the return to the roots of society, former institutions and customs, creative work, cooperation, mutual help and unity of its members and social groups, then revolution comes to its logical end. Characterizing revolutions, Sorokin calls them the great tragedy and "the worst way of improving material and spiritual conditions of masses' lives" (Sorokin, 1992b), because they are followed by violence and cruelty, the reduction of freedom, deformation of the social structure, the worsening of the economic and cultural situation of the working class, and the disintegration of society as a whole. Sorokin claims that thoughtful and consistently implemented reforms, not revolutions, can be the only right way to improve and reconstruct social life.

Sorokin's book *Social Mobility* (1927), innovative in its genre, still remains the classical work on the problem of social stratification and mobility. The terminology introduced by Sorokin is universally recognized. He describes the world as social space, filled with social ties and relations. In this space, representing a system of multiple coordinates, there are two main axes – axis X (i.e., horizontal measurements) and axis Y (i.e., vertical measurements). The stratification principle lies in the basis of the inner organization of social space. Sorokin suggests the following definition for social stratification: "Social stratification means the differentiation of a certain given totality of population into hierarchically superposed classes. It is displayed in the presence of the highest and lowest layers. Its basis and essence consist in uneven distribution of rights and privileges, duties and responsibilities, social welfare and hardship, social power and influence among the members of this or that society" (Sorokin, 2005). There are three main systems of social stratification, as a rule, closely connected to one another: the economic, the political, and the occupational. Sorokin states that social stratification is a constant characteristic of any organized society. Albeit changing in form, social stratification exists in all societies that declare equality of people. Social mobility is also a normal and natural state of society. It is understood by Sorokin as "any transition of an individual or social object or value from one social position to another" (Sorokin, 2005). In Sorokin's view, there are two different types of social mobility – horizontal and vertical. Horizontal mobility concerns transition from one social position to another, situated on the same level. Vertical mobility refers to transitions of people from one social stratum to one higher or lower in the social scale. According to the direction of the transition, two types of vertical mobility can be spoken about: ascending and descending. They imply social rise and social fall. Vertical mobility is considered by Sorokin to correspond to the three forms of social stratification: economic, political, and occupational. The most important channels of vertical mobility are social institutions such as the army, the church, schools, economic, political, and occupational organizations, family, and matrimony. These are peculiar 'social lifts,' as a rule, working like 'sieves,' which sift individuals, allowing some of them to go up and keeping others in the lower strata. Social stratification and mobility in society are predetermined by the fact that people are not equal, physically and mentally. Joint activity of individuals requires hierarchical organization.

In the work *Contemporary Sociological Theories* (1928), which set Sorokin apart from his colleagues with its encyclopedic sweep, he takes a review walk through 'the forest of sociological theory,' where we can find beautiful and healthy plants and flowers (which should be used in our work) alongside their barren counterparts (which should be avoided). A number of sociological schools (mechanistic, geographical, demographical, biopsychological, sociologism) are outlined in the book. Some of them have disappeared under modern conditions (e.g., socio-Darwinism) and some of them have been transformed by reconsidering their main principles (e.g., the mechanistic and biopsychological schools). Sorokin offered an operational definition of sociology, with different aspects of which all of the general schools concern themselves: "Sociology is a study, first, of the relationship and correlations between various classes of social phenomena (correlations between economic and religious; family and moral; juridical and economic; mobility and political phenomena and so on); second, that between the social and the non-social (geographic, biological, etc.) phenomena; third, the study of the general characteristics, common to all classes of social phenomena" (Sorokin, 1928). *Contemporary Sociological Theories* is the work which had been served as a textbook in many American universities for a long time.

Sorokin's ideas finally took the shape of his integral model, presented in the four-volume *Social and Cultural Dynamics* (1937–41). According to the integral model, any society can be understood only by studying its culture; that is, a system of meanings, norms, and values, emerging under the influence of the dual biosocial nature of the individual, and integrating into a united mental style. This style is characterized by the following key features: ideas about the nature of reality and the way of knowledge, by which they are obtained; the character of individuals' main goals and needs, the degree and manner of their satisfaction. According to Sorokin, there are three main sociocultural types: ideational, sensate, and idealistic. Each of them is characterized by its own forms of art, literature, truth and knowledge, legal consciousness, and ethical and social relations. The ideational sociocultural type is characterized by the following features: reality is represented as spiritual and eternal essence; the rational way of knowledge predominates; goals and needs are spiritual, and their satisfaction is the highest possible achievement; the manner of their satisfaction is characterized by curbing carnal and material needs up to the complete refusal of sensual temptation. Thus, the ideational sociocultural type is characterized by 'the beyond' orientation, revealing itself in the predominance of transcendental values and the acknowledgment of the earthly life as but a temporary refuge. The sensate sociocultural type is characterized by

opposite features: reality is represented as material and changeable essence; the sensual way of knowledge predominates; goals and needs are carnal and material, and to satisfy these is the highest possible achievement; the manner of their satisfaction "doesn't consist in the transformation or exploitation of individuals' spiritual world, but it consists in the transformation or exploration of the outer world" (Sorokin, 2000). The sensate sociocultural type is characterized by an 'earthly' orientation, revealing itself in the predominance of hedonistic values and the acknowledgment of earthly life as the highest reality. If there is an organic balance between spiritual and sensual elements, the intermediate sociocultural type, that is, the idealistic, appears. Reality is represented as both spiritual and material essence; the intuitive way of knowledge predominates; material needs and goals are subordinated to spiritual ones, the way of their satisfaction consists both in self-improvement and in transformation of the outer sensually perceived world. Historical development is a cyclic fluctuation of these three sociocultural types. Sociocultural fluctuations are the processes recurring from time to time in the history of social and cultural life.

Sorokin's interest in the problems of sociocultural dynamics is connected with the crisis of modern culture. It is investigated in works such as *The Crisis of Our Age* (1941), *Man and Society in Calamity* (1942), *Society, Culture and Personality* (1947), and *S.O.S. The Meaning of Our Crisis* (1951). The themes of these works were partly influenced by the Second World War. According to Sorokin, these are the three important trends of the modern epoch. The first trend consists of the shift of humankind's center of creative leadership from Europe to the wider sphere of the Pacific and Atlantic coasts, especially to America, Asia, and Africa. The second trend consists of the disintegration and the decline of the modern sensate sociocultural type. In Sorokin's opinion, the twentieth century is "the most bloody of all the previous 25 centuries of Greek-Roman and Western history" (Sorokin, 1997). In connection with the domination of sensual values and in the absence of a clear differentiating line between positive and negative phenomena, the number of interindividual and intergroup conflicts grows, the state of social anomie, which causes wars, revolutions, crime and violence, emerges. Hence, the third trend consists of the emergence and development of a new integral sociocultural type. Sorokin opposes the fruitless and destructive forces of the dying sensate formation, the main function of which is natural exploration, to the creative forces of the emerging integral formation, the main function of which is ennoblement and humanization of the individual.

Sorokin also foresaw the basic trends of the development of Russian–American relations in the twentieth century. In the comparative research piece *Russia and the United States* (1944), he noted numerous sociocultural similarities between these two countries. They are both characterized by unity in diversity as "melting pots of diverse racial, ethnic, national and cultural groups and peoples" (Sorokin, 2007). Their mentalities, moral standards, and the democratic structure of the main sociocultural institutions (family, legal and judicial systems, government, and religious institutions) are very much alike. That is why Russia and America can mutually influence each other. Russia can enrich American culture and the United States in turn can help Russia to put an end to violations of human rights. The book *Russia and the United States* was republished in 2007 with a new introduction by Edward A. Tiryakian who states that this work has cardinal meaning for the international order of the twenty-first century (Tiryakian, 2007). Tiryakian produces the following proof in confirmation of Sorokin's prophetic abilities: "he was right in the conclusion about the possibility of a firm peace between the two countries in spite of the ideological statements of the Cold War era. Fortunately, that war did not develop into the 'hot' war and the triumph of political democracy and the free market system have made Russia the mirror image of the US" (Tiryakian, 2007). Unfortunately, nowadays, in the beginning of the twenty-first century these two great countries stand on the cusp of a new ideological and informational war connected with the miscommunication and controversial views on the current situation in Ukraine and Crimea.

In his latest works connected with the functioning of the Harvard Research Center in Creative Altruism – *Altruistic Love* (1950), *S.O.S. The Meaning of Our Crisis* (1951), *The Ways and Power of Love* (1954), *American Sex Revolution* (1956), *Power and Morality: Who Shall Guard the Guardians?* (1959) – Sorokin states that the most important way to overcome the crisis and immorality of modern civilization is the moral reconstruction of humankind, in which altruistic love plays the most significant part. Despite that Sorokin's activity in the sphere of creative altruism did not take its proper place in the American academic environment (for instance, Coser regards it as Sorokin's 'later retreatism' (Coser, 1977, 2006)), he himself appraised it highly (as some American sociologists would also come to do later (Johnston, 1991; Nichols, 1999)). Sorokin spoke against the Cold War between the USSR and the United States and against the Vietnam and the Korean Wars.

Lasting Impact

Sorokin's ideas are required by the present scientific community due to the current realities, namely, the fight against the global financial crisis, international terrorism, and the spread of nuclear weapons.

The Pitirim A. Sorokin Foundation (http://www.sorokinfoundation.org or http://www.cliffstreet.org; http://www.pitirimsorokin.org (in Russian)) was established by his younger son, Dr Sergei P. Sorokin, in 2011 in Winchester, Massachusetts in order to promote and support interest in Sorokin's sociological legacy by carrying on different scientific and literary activities in the United States and in Russia. The work of the Foundation is superintended by its executive director, Dr Pavel P. Krotov.

The new section of the American Sociological Association on Altruism, Morality, and Social Solidarity (http://www.asanet.org/sections/altruism.cfm and https://sites.google.com/site/altruismmoralitysolidarity/) was also organized in 2011 by Vincent Jeffries, emeritus professor of sociology at the California State University, Northridge for running the tasks of the study, critical assessment, and advancement of ideas developed by Sorokin in the 1950s and 1960s. Its present chair is Matthew T. Lee, professor of sociology at the University of Akron. Modern American sociologists state that the study of altruism and social solidarity as an area of specialization in

sociology could make a great contribution to the discipline and to society as a whole (Jeffries et al., 2006). Many Russian sociologists are the current members of this ASA section.

In addition to the renewed interest in Sorokin's later work on altruism, his writings on civilization have also become a focus of social science studies and current rethinking and reinvigoration of the sociological tradition of civilizational analysis (Weber, Durkheim, Mauss, Sorokin, Elias, Nelson, Huntington, Eisenstadt), in Samuel P. Huntington's *Clash of Civilisations?* (1993) and in the research indicated in Said A. Arjomand and Edward A. Tiryakian's *Rethinking Civilizational Analysis* (2004). Such interest results from the changing demographic, political, and economic reality of the world, as it enters a new phase.

A lot of charitable, scientific, and educational events, taking place in Moscow, St Petersburg, and Syktyvkar, are evidence of the continuing renaissance of Sorokin which began in the 1990s in his historical homeland, Russia, after long-term neglect of his ideas in the USSR. The unique documents, photographic and film materials from the Sorokin family archive were displayed for the first time in Russia, in the documentary film *The Antithesis of Pitirim Sorokin* aired on the Culture Channel in April 2009. The Faculty of Sociology at Lomonosov Moscow State University (http://www.socio.msu.ru/) regularly hosts the International Conference 'Sorokin Readings' and owns the expert and analytical portal 'Pitirim Sorokin Foundation' (http://www.sorokinfond.ru/). Pitirim Sorokin – Nikolay Kondratieff International Institute (http://www.misk.newparadigm.ru/; http://www.eng.newparadigm.ru/index.html) founded in 1999 and headed by Professor Yu V. Yakovets carries on activities on publishing Sorokin's works, conducting international conferences, and developing long-time socioeconomic forecasts on the basis of the integral macroforecast methodology. Sorokin is widely studied nowadays by Russian students within the framework of such lecture courses as 'History of Russian sociology,' 'History of classical sociology,' and 'Current sociological theory.' The numerous articles by Sorokin and about him are constantly published in the prestigious Russian sociology journals *Sotsiologicheskie issledovaniya* (*Sociological Research*) and *Sotsiologiya* (*Sociology*).

Source Monitoring

Sarah E MacPherson, Centre for Cognitive Ageing and Cognitive Epidemiology, Human Cognitive Neuroscience, University of Edinburgh, Edinburgh, UK

Abstract

Source monitoring is the ability to reconstruct and assess the amount and quality of contextual details that are to be remembered. Source monitoring can be classified in terms of internal, external, or reality monitoring judgments depending on the type of source judgments being made. Evidence from patients and neuroimaging studies, as well as developmental research, suggest source monitoring is associated with the frontal and medial temporal lobes. However, there still remains a debate in the literature whether these brain regions are necessary for source monitoring and whether distinct neural mechanisms underlie different source judgments.

Source monitoring refers to the ability to remember the conditions or context under which a memory was formed. Source monitoring can be classified into three groupings: internal, external, and reality source monitoring. *Internal source monitoring* requires individuals to discriminate between events generated from internal sources of information through their own actions or thoughts (e.g., "Did I actually switch off the oven or only imagine that I did?"), while *external source monitoring* refers to differentiating between memories externally produced by other people (e.g., "Did Sally or Jill switch off the oven?"). *Reality monitoring* is the ability to discriminate between sources of information generated internally and externally either in terms of self- versus other-generated information (e.g., "Did I switch off the oven or did Sally?") or implicit, internally derived aspects of memory (e.g., imagining the act of switching off the oven) versus more explicit, externally derived aspects of memory (e.g., perceiving someone else or switching off the oven yourself). Failures in source monitoring, such as an inability to differentiate between different sources of information (e.g., uncertainty about whether you actually switched off the oven or simply imagined that you did), can have serious consequences on everyday life. Source monitoring has been studied in the research areas of fundamental and applied memory including amnesia, neurological disorders, false memory and eye witness testimony, legal decisions, developmental memory, and cognitive aging.

Cognitive Theories of Source Monitoring

Source Monitoring Framework

The source monitoring framework proposes that item and source memory constitute the episodic memory system (see Johnson et al., 1993). While item memory relates to the ability to recall or recognize information that was presented earlier, source memory involves the recollection of the contextual details of a memory. In the late 1980s and early 1990s, research demonstrated that item memory and source memory were functionally dissociable. In certain situations, individuals who could consistently recall the content of information they learned, were not able to recollect the context associated with learning that information such as how they came to know a particular piece of information. The source monitoring framework proposes that individuals do not necessarily explicitly associate their memories with context. Instead, they retrieve and assess an association between the qualitative aspects of a memory (e.g., the perceptual, spatial, or temporal details, semantic concepts, emotional reactions, or the *cognitive operations* associated with elaborating and organizing information during encoding). In making source monitoring judgments, individuals evaluate the amount and quality of these details compared to an average or anticipated measure of detail for a particular memory type. Different types of source monitoring judgments vary in terms of these details depending on the task context, an individual's intentions, past experience, etc. External sources of information tend to have more perceptual, spatial, or temporal features (e.g., remembering the word was red) but fewer cognitive operations compared to internal sources of information (e.g., remembering that you thought about something red when the word was presented). Perceptually experienced situations may have more egocentric rather than allocentric spatial features compared to internal, imagined events. Source monitoring judgments are typically made using fast, automatic heuristic decision-making processes, although slower, controlled systematic processes can also be used. Both heuristic and controlled processes are influenced by prior knowledge and beliefs (e.g., the qualitative details a source memory of that type should have). In addition, the social and cultural circumstances in which memories are assessed influence what we remember, the frequency we do so, and what we consider to be fitting evidence that an event has actually been remembered. For example, a witness to a crime may focus on specific details of the perpetrator's appearance, where and when the crime took place and whether the details are credible. In contrast, a person discussing their wedding day might concentrate less on particular perceptual and temporal details and more on familiarity and emotional details. While the details in both situations may be encoded in the same way initially, distinct characteristics such as the perceptual and the emotional aspects may be weighted differently and the extent to which heuristic and systematic processing influence the memory differs depending on the required social situation. Furthermore, as source monitoring is typically based on judgment processes rather than on direct retrieval, motivational features may also influence the details that are first attended to

 http://dx.doi.org/10.1016/B978-0-08-097086-8.51062-9

and then retrieved or given the most importance to after the event when later remembering.

Source Monitoring Assessment

Various paradigms have been devised to assess the different types of source monitoring judgments. To assess external source monitoring, individuals are generally presented with items that differ in terms of certain features during the study phase which might include location (e.g., above or below or to the left or the right of a cross in the center of a computer screen), time period (e.g., series one or series two of a study list), form (e.g., male vs female speakers or red vs blue fonts), or sensory modality (e.g., oral vs visual). At test, participants are then required to remember the contextual information associated with the to-be-remembered items. In internal source monitoring, individuals are required to discriminate between memories generated from internal sources (e.g., words generated from anagrams vs words imagined on a computer screen). In reality monitoring, individuals have to determine whether items were generated internally or externally in terms of the self (e.g., words they said or imagined) versus other (e.g., words someone else said) or implicitly (e.g., generated from an anagram or imagined) versus explicitly (e.g., words or pictures presented on a computer screen).

Although these source monitoring tasks explicitly focus on identifying the source of information, there are other tasks that are also thought to involve source monitoring processes such as remember/know judgments; context, relational, or associative memory tasks; memory binding tasks; inclusion/exclusion tasks; list discrimination; and any recall and recognition tasks, which require information from a particular source to be identified. The conditions for making source monitoring decisions vary and depend on the purpose of the source judgment at the time it is made.

Source Monitoring Errors

On occasions, individuals fail to differentiate between what actually took place and what they deduced or imagined, what they perceived and what was proposed to them, the actions of different individuals, and newly learned and previously known information. Difficulties with source monitoring occur because source judgments are based on evaluations of the details to be remembered rather than explicitly recalled memories. If the information is poorly encoded and, as a result, the information is incomplete or unclear, or there is disruption in the evaluation or retrieval of the memory, source monitoring errors can arise.

Source monitoring errors are also more likely to occur when there is a high degree of similarity between memories from two sources. Potential similarities might include two voices of the same gender, when words that are perceived or imagined are synonyms (e.g., jewel or gem) or line drawings that are perceived or imagined are visually similar. When individuals make these source errors, they are also inclined to borrow details from the encountered items including their color or their position on a computer screen. This means that associations between item memories can also influence source memory judgments. Other reasons for source errors might include a more relaxed criterion being used to evaluate memories, fewer qualitative aspects being used or details incorrectly evaluated, or source judgments being made under time pressure.

The Generation Effect

In memory research, it is generally agreed that asking individuals to generate the information they have to remember results in the information being better remembered than nongenerated information. This is known as the *generation effect*. Self-generation can be achieved through the generation of words from fragments, antonyms, or synonyms, keywords from paragraphs or pictures, or the answers to numerical problems. The process of generating items is thought to strengthen the encoding of the item-specific, semantic, or relational features of the stimulus, which results in better memory for those items (see Mulligan and Lozito, 2004 for a review).

Yet, whether this generation effect can also be applied to source monitoring judgments remains a topic of debate as generating words does not always lead to positive benefits for source memory. In some instances, an item-context trade-off is found where generating answers to questions benefits item memory, whereas reading statements benefits source memory. Therefore, item and source memory processes may be dissociable where generation provides benefits to item memory at the expense of source memory. Or it may be that different encoding strategies affect contextual details differently, as reading highlights the importance of the perceptual details of an item (e.g., color or font) whereas generation underlines the importance of conceptual or nonvisual information (e.g., location). A final consideration is that generation effects for source memory depend upon the type of source monitoring task adopted, as positive generation effects occur more often in reality-monitoring tasks, whereas negative generation effects occur more often in external source monitoring tasks.

Research has also focused on the contribution of cognitive operations to the generation effect. Early work in relation to the generation effect focused on cognitive effort rather than cognitive operations, where the more effort associated with generating items, the stronger or more characteristic (and therefore more easily accessible) the memory traces compared to nongenerated items. In addition, remembering the cognitive operations involved at study might benefit the retrieval of the generated information. The size of the generation effect (i.e., generated vs nongenerated items) was thought to be proportionate to the cognitive effort necessary to produce these generated items.

However, as the generation effect is not always found for more difficult items that require more cognitive effort or nonwords, cognitive effort cannot fully account for the generation effect. This meant that the literature moved away from focusing on cognitive effort, and toward a focus on cognitive operations. Cognitive operations might include processes that influence the reading of the items presented by the experimenter or influence the search and decision strategies

important for generating the materials (see Johnson et al., 1993). Harder encoding conditions involving more cognitive operations to generate items compared to easy encoding conditions (e.g., Was an anagram created or deciphered?) result in more successful source monitoring judgments. However, the same advantage is not found when individuals are asked to judge whether the anagrams are easy or difficult during the source monitoring test (see Foley and Foley, 2007). Overall, these findings suggest that both the encoding task and the cognitive operations involved in source monitoring tasks influence the strength and direction of the generation effect.

Source Monitoring Framework versus Dual-Process Theories

While dual-process theories of memory are discussed in the section on recognition memory, it is important at this juncture to discuss how such models differ from the source memory framework, as dual-process theories of memory are also thought to influence source monitoring (e.g., Eichenbaum et al., 2007; Wixted, 2007). Several dual-process models argue that episodic memory retrieval is dependent on two independent processes: recollection, which involves remembering certain details about the experience that the item was encountered and familiarity, which is a feeling that an item has already been presented but no additional information can be retrieved (Jacoby, 1991). Recollection is considered an all-or-none, threshold process where someone can either recollect information or not, whereas familiarity is a continuous, graded process that can vary by degrees. Successful source monitoring judgments are thought to rely on recollection where individuals make decisions about the contextual characteristics of a previously presented item (e.g., temporal, spatial, semantic). Both the dual-process and source monitoring framework models agree that recollection and familiarity can contribute to a memory judgment. However, while the dual-process models of memory consider recollection and familiarity as two separate processes that give rise to subjective experience, the source monitoring framework refers to recollection and familiarity as types of subjective experience and assumes that both are continuous, graded processes. Often the proportion of correct source monitoring judgments associated with recollection- and familiarity-based judgments does not differ, which suggests that the absence of recollection details does not prevent correct source attributions and familiarity also plays a role in source monitoring. Nonetheless, the dual-process models have mainly focused on situations where recollection is successful or not.

Dual-process theories of memory also differ from the source monitoring framework in terms of false memories. The source monitoring framework emphasizes that memories are based on features that are bound together during a particular event and the memories we produce are instilled with our knowledge, ideas, desires, and aspects of our imagination. According to the source monitoring framework, true and false memories can be explained using the same broad principles of memory (see Lindsay, 2008), and so recollection does not guarantee that accurate memories have been retrieved. Inaccurate source monitoring judgments involve source information that is generated by the self or from prior knowledge or information that is introduced from other items. In contrast, dual-process theories claim that inaccurate source monitoring judgments occur when the memory decision is based on familiarity and not recollection (e.g., Wais et al., 2008). As dual-process models tend to focus on the divergence between recollection and familiarity, the source monitoring framework focuses on explaining the details of true versus false recollection; this has led to some of the noticeable distinctions between the two theories.

Source Monitoring for Emotional Context

Another important issue associated with source monitoring is the influence of emotional information on source monitoring judgments. An individual who survives a life-threatening car accident might remember external contextual details directly associated with the emotional event (e.g., the other car), external details not directly associated with the emotional event (e.g., the road they were driving along), or internal details associated with their thoughts and feelings (e.g., feeling faint, worrying about damage to the car). Despite the fact that remembering emotional source information may often benefit individuals when they have to differentiate between their own and other people's memories, the processing of emotional information may also occur at the detriment of other information that provides better source cues. Indeed, while emotional items tend to be recalled and recognized better than neutral items, the influence of emotion on source memory varies depending on the type of source monitoring judgments being made. Source monitoring has been shown to improve when individuals have to remember the perceptual features of emotion words (e.g., font color) and yet decline for other contextual features (e.g., location or whether the information was seen or heard). It has also been shown that when participants emotionally focus on the self or another person when encoding emotional statements provided by one of the two speakers (e.g., how the participant feels about what two speakers are saying or how the speakers themselves are feeling), item memory is better for the self-focus condition compared to the other-focus condition, whereas source memory is poorer for the self-focus condition (e.g., Johnson et al., 1996). As individuals concentrate on the inner self and how they feel, emotional information is thought to draw attention away from external, perceptual information such as voice quality. This reduces the probability that the participant will bind the perceptual attributes of the speaker (e.g., voice sound, voice quality) to the content of statement made, resulting in a negative effect on source memory. Alternatively, if individuals focus on the other person's emotions while encoding information, the binding of the perceptual features associated with the speaker and the content of the statement allows for accurate source monitoring judgments (see Kensinger, 2007).

Patient Studies and Source Monitoring

Up until this point, the review has focused on source monitoring abilities in healthy individuals. However, to enhance our understanding of source monitoring processes, it is also

important to discuss the effects brain damage can have on source monitoring abilities. It was the early twentieth century when Claparède, the Swiss neurologist, first reported a case of alcoholic Korsakoff's syndrome who had a profound amnesia for recent events. More importantly, even when the patient was able to recall factual information, she did not believe that she had learned the information from Claparède himself and would adamantly dispute the fact that she had been read a story to recall. This inability to remember the origin of learned factual information and associating it with learning prior to, rather than during, the experiment is often referred to as *source amnesia*.

Since then, source errors have been reported in a number of single-case reports demonstrating dissociations between item memory and source memory. This led Schacter et al. (1984) to develop a paradigm for investigating source monitoring in patient groups. In this paradigm, individuals are asked questions regarding fictional characteristics about famous and unknown individuals by one of two experimenters and the correct answer is then provided. The question is then repeated again at a later point by one of the two experimenters and the participants not only have to provide the correct answer to the question, but also how they learned that information. This paradigm demonstrated that even if amnesic patients are able to recall learned fictitious factual knowledge, source recall remains low and patients tend to attribute learning knowledge to another situation rather than from one of the two experimenters within the experiment itself. However, not all amnesic patients demonstrate source amnesia, and even in those that do, its severity is not necessarily associated with the severity of their memory deficit (e.g., Shimamura and Squire, 1987). Therefore, amnesic patients can show a severe impairment in item memory in the absence of source monitoring deficits.

Medial Temporal Lobes

In terms of the neural basis of source monitoring, the medial temporal lobe, in particular the hippocampus, is thought to play an important role in episodic memory. However, research suggests that the role of the medial temporal lobe is to support both item and source memory to the same extent and the medial temporal lobe is not *necessary* for source monitoring performance. Although some medial temporal lobe patients demonstrate impaired source monitoring abilities when matched with healthy controls on item memory, there are also instances where patients with more focal hippocampal lesions do not necessarily differ from controls in terms of source monitoring performance. Furthermore, the lack of an association between item memory and source amnesia in amnesic patients led Shimamura and Squire (1987) to conclude that source monitoring relies on brain regions other than the medial temporal lobe.

Frontal Lobes

Frontal lobe lesions have also been associated with deficits in source monitoring abilities. A number of studies have demonstrated that item and source memory are dissociable in terms of frontal lobe involvement, as impairments in source memory can be found in the absence of item memory deficits. Luria (1976) first reported a frontal patient with source amnesia due to the rupture of an anterior communicating artery aneurysm. While the patient could remember picture-word paired associates 2 days and 1 week after learning them, he had no knowledge of how he came to learn these associations. Therefore, his memory for facts was intact but he had impaired memory for source information.

Luria's single-case report led to a number of studies investigating source monitoring in groups of frontal patients. Using a similar paradigm to that of Schacter et al. (1984), Janowsky et al. (1989) conducted one of the first source memory studies involving frontal patients. They demonstrated that although frontal patients could learn new information, they incorrectly attributed the source of that information more often than controls. These findings provided further support that patients with focal frontal lobe lesions are able to learn and remember new information but not remember the context in which the information was learned.

The role that the frontal lobes play in source monitoring decisions has been considered in terms of Johnson et al.'s (1993) source monitoring framework. Source monitoring is thought to require varying amounts of strategic search and judgment depending on how well the information is encoded. As frontal lobe lesions are thought to impair the ability to strategically search during memory retrieval, frontal-related deficits in source monitoring may be secondary to the strategic processing demands of the memory tasks involved. Indeed, when the strategic demands of the source monitoring tasks are reduced, frontal patients do not appear to be significantly impaired on item or source memory.

Furthermore, frontal lobe lesions do not always result in source monitoring deficits. There are also reports of amnesic patients whose source amnesia is more related to their amnesia severity rather than their performance on measures of frontal lobe function – although there are other studies that have reported significant correlations between source monitoring performance and measures of frontal lobe function. As the frontal lobes are a large, heterogeneous brain region, it may be that only certain subregions within the frontal lobes are associated with source monitoring. However, few patient studies have examined whether this is the case or not. Dorsolateral prefrontal lesions have resulted in difficulty remembering temporal contextual details compared to frontal patients with more medial lesions. Yet, ventromedial prefrontal lesions produce impairments in memory for perceptual but not semantic features. Therefore, different neural mechanisms may underlie distinct contextual features but further work is necessary to ascertain what these are.

Source Monitoring and Confabulation

Confabulation is a clinical syndrome, which is associated with orbitofrontal and medial frontal lobe lesions and typically results in source monitoring deficits. Confabulations are usually produced by amnesic patients with ruptured anterior communicating artery aneurysms, although they are also associated with other clinical syndromes such as Alzheimer's disease, frontotemporal dementia, Korsakoff's syndrome, neglect, and schizophrenia (for a review see Johnson et al.,

2000). Confabulations are classified as false accounts or statements about the self and/or the world that inadvertently occur due to an underlying pathological condition. Different accounts have been proposed to explain confabulation including deficits in memory control processes (strategic retrieval hypothesis: e.g., Burgess and Shallice, 1996) or confusion of the temporal context of events (temporality accounts: e.g., Schnider, 2003) or failure to distinguish between real and imagined events (source or reality monitoring accounts: e.g., Johnson et al., 1993). Those supporters of the reality monitoring account of confabulation state that confabulators cannot source their memories in terms of where or when the event took place and this leads to errors. Clinical descriptions of confabulating amnesiacs tend to be consistent with the notion that reality monitoring engages in both heuristic and systematic decision-making processes (Johnson, 1991). Reality monitoring failures associated with heuristic errors are produced by unusually striking mental experiences or a relaxed criterion being used to evaluate the retrieved memory, making it more likely the memory will be judged as real. Initially, the qualitative aspects of the memory may pass the heuristic reality-monitoring assessment, but then they are properly assessed by more systematic processes that test whether the memory is reliable, credible, and reasonable. Bizarre, implausible confabulations are thought to be the result of disturbances in systematic processing where vivid thoughts that have passed the heuristic reality monitoring examination are not identified.

Yet, the source monitoring account cannot sufficiently explain confabulation, as it cannot explain confabulations that only occur in episodic and not semantic memory. According to the source monitoring framework, confabulation should occur when any decision about the source or reality of a memory is needed. However, source monitoring framework theories have argued that there are differences in task difficulty in terms of well-encoded semantic information and more complex personal episodic memory and this is why some confabulators only show deficits on episodic memory tasks. Research has shown that confabulators have source monitoring deficits in terms of temporal order, spatial features, and distinguishing between the visual and auditory modality. Nonetheless, such source monitoring tasks do not differentiate confabulators from nonconfabulating amnesiacs and source monitoring deficits are found in other brain damaged groups who do not confabulate. Johnson and her colleagues point out that they are not suggesting that source monitoring deficits are the only impairments associated with confabulation but only one of a number of deficits that are necessary for confabulation to occur.

Source Monitoring and Neuroimaging

Neuroimaging studies involving functional magnetic resonance imaging provide another source of evidence for the mapping of source monitoring processes onto different neural mechanisms (see Mitchell and Johnson, 2009). Activation in the hippocampus (and parahippocampal region) increases when encoding and retrieving items for which the source is later successfully remembered compared to when the source is not successfully remembered. This activation is thought to be common to words, objects, and scenes, both at study and test, suggesting that these source memory effects are domain-general. In contrast, material-dependent source memory effects at study, but not test, have been reported for objects only in the left perirhinal cortex. Furthermore, the majority of neuroimaging studies provide evidence for medial temporal lobe activation during recollection-based judgments, but in the perirhinal cortex during familiarity-based judgments.

Frontal Lobes

In terms of frontal lobe activation, neuroimaging studies also suggest that the frontal lobes are associated more with source than item memory. More specifically, the dorsolateral prefrontal cortex is activated while encoding and retrieving source information (e.g., color, position) compared to item information. Work has also shown that this prefrontal activation is not limited to the type of features to be remembered, suggesting that the dorsolateral prefrontal cortex is involved in domain-general decision-making (e.g., Dobbins and Han, 2006).

While functional magnetic resonance imaging studies suggest that subregions within the frontal lobes play distinct roles in source monitoring, a conclusion to what these different roles are has yet to be reached. In some work, the left prefrontal areas have been associated with systematic source monitoring processes or strategically using contextual information to make a decision (i.e., recollection), while the right prefrontal areas have been associated with heuristic source monitoring processes or familiarity-based decisions where individuals have a decontextualized feeling that an item has previously been presented. Other research has suggested that the right dorsolateral prefrontal cortex is important for controlled, systematic postretrieval monitoring processes. Therefore, the question of whether it is the left or the right dorsolateral prefrontal cortex that is involved in systematic source monitoring processes remains unanswered.

In addition to dorsolateral prefrontal activation, the medial prefrontal cortex is activated during *origin* but not *context* reality monitoring. Origin reality monitoring is where self versus other judgments are made while, context reality monitoring is where perceived versus imagined source judgments are made. In particular, origin monitoring is thought to be associated with significantly more activation in the rostral prefrontal cortex (Brodmann area 10) compared to context monitoring (Simons et al., 2008). This is not surprising given that Brodmann area 10 is thought to be the gateway between processing perceptual or reflective information, which is likely to originate from the self.

Event-Related Potentials

Imaging methods measuring electrical brain activity have also been used to examine source monitoring processes where memory-related and event-related potentials can be discriminated between in terms of temporal onset (i.e., the time after test probe) and spatial location. One of the largest amplitude differences between target and distracter items in source event-related potential studies emerges approximately 800 ms after

the probe is presented in the right frontal region. This is referred to as the *right frontal effect*. This component is thought to reflect postretrieval processes or monitoring processes that are analogous with the decision processes proposed by the source monitoring framework. In addition, an earlier onset old/new event-related potential component at the left parietal electrode sites has also been reliably reported, which has a temporal onset approximately 600–800 ms after the probe is presented. This is referred to as the *parietal effect*. It is linked with activation in left inferior parietal cortex and is thought to reflect recollection. Finally, a third event-related potential component is reported in some source monitoring studies, which is referred to as the *late posterior negativity effect* and has a temporal onset of approximately 1000 ms. This late posterior negativity effect has a more negative amplitude for targets compared to distracters with the largest amplitude difference at posterior electrodes sites. The late posterior negativity effect is thought to reflect further examination of the combinations of features retrieved during demanding source judgments. However, although these three event-related potential components are associated with old/new source judgments, when they are examined in terms of correct versus incorrect source judgments, only the increase in the magnitude of the parietal effect has been associated with accurate source monitoring judgments.

While the majority of event-related potential studies have investigated the components of external source monitoring, there are also studies that have focused on reality monitoring. These studies have used paradigms that typically compare words generated versus heard, actions performed versus watched, and perceived versus imagined pictures. A larger parietal effect has been associated with internally generated sources compared to externally generated. However, it remains uncertain whether this parietal effect is because internally generated items encourage more vivid, strategic recollection or they involve more cognitive operations to create the mental representations for that event which individuals can direct themselves toward during remembering. Externally generated information and distracters do not have this targeted information.

In contrast, the right frontal effect is less consistently reported in reality monitoring studies, with only some event-related potential studies reporting bilateral frontal effects associated with making old/new judgments. It has been suggested that the lack of an old/new frontal effect might be because new items produce more positive event-related potentials during reality monitoring compared to externally generated items. Indeed, neuroimaging has reported left anterior ventrolateral prefrontal activation and medial anterior prefrontal activation when making internal source monitoring judgments. Further work is needed to determine whether the discrete frontal event-related potentials across studies are due to different qualitative features of internal sources or more general monitoring processes that are associated with distinct prefrontal regions.

Developmental Studies of Source Monitoring

Source Monitoring in Children

Further clues toward understanding source monitoring processes can be taken from research investigating how source monitoring abilities develop and change with age (see Johnson et al., 1993; Newcombe et al., 2007). A child-friendly adaptation of Schacter et al.'s (1984) paradigm has shown that 4-year olds produce a significantly greater number of extra-experimental errors than 6- and 8-year olds where they claimed they had learned the information outside the experimental situation (Drummey and Newcombe, 2002). As source amnesia is associated with frontal lobe dysfunction, these changes in source monitoring abilities between 4 and 6 years of age may reflect the maturation of function within the prefrontal cortex. Other developmental studies have compared different types of source monitoring abilities within the same group of young children and have shown that, in some paradigms, they are able to perform as well as adults. In studies asking children to perform, imagine, or perceive someone else performing an action, children do not make external monitoring errors (i.e., distinguishing between two individuals performing particular actions) or reality monitoring errors (i.e., judging whether they performed the action or someone else). However, they are more likely to make internal source monitoring errors where they mix up performing and imagining the action themselves (e.g., Foley and Johnson, 1985). This difficulty, children have with internal monitoring judgments, is likely to be due to the difficulty in distinguishing between similar sources (e.g., Lindsay et al., 1991).

Source Monitoring in Healthy Adult Aging

At the other end of the developmental spectrum, the majority of studies on healthy adult aging have demonstrated that age has a detrimental effect on source monitoring abilities (see Mitchell and Johnson, 2009). Although older adults are able to remember learned fictitious general knowledge facts, they have difficulty remembering whether these facts are learned during or prior to the experiment. Like young children, they are more likely to make source amnesia errors where they attribute information learned within the experiment as being learned outside the experiment. However, age-related source monitoring deficits are not reported in all cases and only apply to particular types of source monitoring. Indeed, significant age differences have been reported when older adults make internal and external source monitoring judgments but not reality monitoring judgments. It is thought that the cognitive operations associated with remembering that an item was produced rather than observed results in different cues, allowing both younger and older adults to successfully distinguish between these conditions. Contrastingly, the cognitive operations associated with remembering an item was produced or imagined are expected to be more alike, thus reducing their success as a cue in distinguishing between what one said from what one only imagined saying. In terms of differentiating between two voices, these judgments rely on the evaluation of perceptual information, as the quantity or type of cognitive operations would not provide a reliable cue for these types of source monitoring judgments. Therefore, in situations where cognitive operations are similar or not beneficial, older adults have to rely on perceptual information and this makes it more difficult to make these types of source monitoring distinctions.

Source memory deficits in older adults may potentially be explained by age-related changes in the brain regions that play

a role in source monitoring such as the medial temporal lobes, prefrontal cortex, and posterior parietal cortex (see Mitchell and Johnson, 2009). When source memory for various types of material is examined in younger and older adults, functional magnetic resonance imaging data have demonstrated that both younger and older adults recruit similar networks of brain regions regardless of the material type, and this includes the parietal cortex, prefrontal cortex, and the hippocampus. Age-related differences in material-independent activation are associated with the right lateral prefrontal cortex, and increases in activation in the perirhinal cortex are associated with improved performance in older adults.

Source Monitoring in Alzheimer's Disease

Research has also examined source monitoring impairments associated with pathological aging. The majority of studies have shown that Alzheimer's disease produces reality monitoring deficits where Alzheimer's disease patients, and to a lesser extent healthy older adults, have been reported to find remembering imagining another person performing an action significantly more difficult than self-performed, self-imagined, and other-performed conditions (e.g., Fairfield and Mammarella, 2009). It is less clear whether Alzheimer's disease affects other aspects of source monitoring. In some cases, Alzheimer's disease patients are not impaired in terms of external source monitoring where they might be asked to remember which one of the two people provided them with information. They are also not reported to show internal source monitoring deficits as they are able to distinguish between self-performed actions or self-imagined actions, or sentences that they themselves have completed or already completed sentences they have read. However, there are also instances where Alzheimer's disease patients are impaired in terms of external and internal source monitoring as they perform poorly on perceptual, spatial and temporal source monitoring tasks with the spatial source monitoring task being more sensitive to dementia. Therefore, while Alzheimer's disease patients are not impaired compared to healthy older adults on all aspects of source monitoring, the degree to which they are impaired on different tasks remains an open question.

In Summary

Research in the areas of basic and applied memory has provided, and will continue to provide, a wealth of experimental data attempting to understand the mechanisms fundamental to source monitoring. According to the source monitoring framework (Johnson et al., 1993), source monitoring relies on the reconstruction and evaluation of the qualitative details of a memory rather than explicitly associating memories with context. This can be done using fast, automatic heuristic decision-making processes, as well as slower, controlled decision-making processes. Lesions in both the medial temporal and frontal lobes have been found to result in source monitoring impairments, although it is less clear whether these brain regions are *necessary* for source monitoring. More recently, functional magnetic resonance imaging and event-related potential studies in healthy individuals have provided further evidence to support frontal lobe involvement in source monitoring judgments. Future work faces the difficult challenge of determining which subregions within the frontal lobes are associated with distinct source monitoring processes. It is only through combining the findings from neuropsychological, functional magnetic resonance imaging, and event-related potential studies that a better understanding of the neural mechanisms that underlie source monitoring might be achieved.

Abstract

The archaeology of South America provides long-term context for problems in many disciplines, including history, anthropology, linguistics, ethnohistory, political science, biology, and ecology. Using a comparison between the Andes Mountains and the Amazon River, this article briefly reviews the history of the discipline, and outlines recent developments. The placement of South American archaeology is considered within scholarship both in South America and around the world.

Introduction

Archaeology is of interest to all scholars of South America because the continent's heritage extends long before historical records. Before the arrival of Europeans at the end of the fifteenth century CE, South American societies included both centralized states with organized political, administrative, military, religious, and economic institutions as well as groups that resisted those same states and/or avoided those institutions. Although it is possible to stretch and cut South American examples to fit universal models of how society or culture works, the archaeological record suggests that the historical particularities of those examples retain explanatory value (Silverman and Isbell, 2008).

The geography of South America can be startling to the outside observer: the Andes Mountains cover a distance equal to that between London and Mumbai, and the Amazon River is as long as a trip from New York to Berlin. These two features provide a simple structure for reviewing archaeological scholarship: Andean archaeology has a longer and richer history whereas Amazonian archaeology is much younger.

South American archaeology is useful to archaeologists from elsewhere in the world, as South America has long been a source of examples and evidence that confounds archaeological models, including classifications of societies and interpretations of process. Early monumental architecture along the Pacific coast is an excellent example, in which groups of people coalesced to erect stone temples as early as 6000 years ago, even in the absence of agriculture or pottery. Many attempts to classify and organize societies around lists of important traits founders on the archaeological record of South America. For example, civilization was once defined by lists of traits, including the use of a system of writing, but the Andean empire of Tawantinsuyu (or Inca) made this criterion irrelevant. The archaeological record is created and used in the present, with archaeologists as one of several kinds of interested parties creating and using it for their own reasons. This rhetorical stance of archaeology makes it more difficult for archaeologists to pronounce the unquestioned truth. The integration of various stakeholders into the conduct and presentation of archaeological research is a central theme in South American archaeology today (*see* Archaeology and Cultural Memory; Ethnic Identity and Ethnicity in Archaeology).

The Amazon and the Andes were central in the definition of cultural areas and regional subdivisions in the broader field of anthropology (Steward, 1946). Exploration of pre-Hispanic heritage began in the second half of the nineteenth century and seems to be tightly, although not always explicitly, linked to the formation of South American nation-states and the consolidation of the industrial era and growth of capitalist economies. On the one hand, having gained independence from Spain, the new nation-states sought to establish their legitimacy as descendants of glorious past cultures and societies. On the other hand, the explorations of these new territories derived from the need of European powers and a burgeoning United States to secure and allocate sources of raw materials for production to sustain thriving industrial economies.

Most nineteenth-century and early twentieth-century expeditions included aristocrats and members of European royal lineages – people wealthy enough to fund their own research. Others were sponsored by different emerging academic institutions and scientific organizations that attempted to include this vast territory within the limits of scientific knowledge. The first research of some of the most emblematic archaeological sites, like Tiwanaku in Bolivia as well as Pachacamac and Machu Picchu in Peru, resulted from these experiences. These expeditions established the foundations of Andean archaeology, and provided the first interpretations of cultural and social variability. Within a debate between evolutionism and historical particularism (*see* Archaeology, Theory in), the historical sequences and chronological frameworks for pre-Hispanic societies established the debates that have guided archaeological research since. Topics such as the peopling of the Americas, the origins of civilizations, relationships of exchange and interaction between peoples of different areas and regions, the processes that led to the domestication of plants and animals or to the development of various kinds of technology (architecture, metallurgy, agriculture, and others) – which therefore influence the development of these societies – remain among the main research questions in Andean archaeology.

The ecological diversity that characterizes the vast region, corresponding to variegated social and cultural historical as well

 http://dx.doi.org/10.1016/B978-0-08-097086-8.13002-8

as linguistic developments, promptly posed a challenge to scholars' explanation of the past. In 1931, Steward was commissioned by the Smithsonian's Bureau of American Ethnography to compile and edit a comprehensive ethnographic reference work on indigenous peoples of South America. The result of his work was an authoritative collection of essays written by renowned scholars that defined ethnographic and archaeological issues and was seminal in the definition of cultural areas. These areas were initially outlined as tentative (Steward, 1946–1950: 228), mostly following ecological criteria although resembling modern geopolitical divisions; this proved the importance of geophysical aspects in the partition of the old colonial territories as part of the process of nation building and explains archaeology's relevance for identity and nationalist enterprises. Later contributions, such as *La Arqueología de la América Andina* (Lumbreras and Batres, 1981), which resulted from an international workshop organized by UNESCO, were crucial in fine-tuning Steward's schema.

Dating the earliest presence of human populations in the Americas has been an ongoing concern of archaeologists. Early on, the debate about the peopling of the Americas was framed within a broader dispute about polygenetic and monogenetic theories of evolution during the last part of the nineteenth century. As a result, this controversy has fueled an intense, even passionate debate about the antiquity of South America's population (*see* North America, Archaeology of). Although debate about this subject continues today, important findings made at Monte Verde in southern Chile (Dillehay, 1997) and more recently on the Pacific coast and lowlands of Bolivian (Lombardo et al., 2013) have shown convincing evidence of earlier peopling of the continent as well as the diversity and complexity of the first South Americans. Most of the evidence found in such sites suggests that South America was populated in different migratory waves, colonizing different regions and habitats, and developing various social and technological strategies of subsistence. Adapting to the climatic changes that took place during the early Holocene (12 000–8000 BCE), groups of foragers sought resources in a shifting and ecologically diverse environment, ranging from the pampas and plains of Patagonia to the Andean mountain chain and its basins, and the lowlands of the Amazon Basin.

The exploitation and consumption of biotic resources, which include a wide range of marine resources as well as camelids and other land game, nuts, tubers, and other plants and vegetables, coincide with the warming of the climate and signal the change of strategies of subsistence, which, according to some authors, led to the specialization of certain groups. Whereas some groups of foragers had attained a specialized economy, like hunting or fishing, others had a more generalized economy, which was complemented with other logistical and opportunistic strategies in order to collect resources. Both of these groups, distinguished mainly by technological features in their cultural assemblages (and characterized mainly by their lithic industries), favored the population of certain areas, leading to the first settlements of the Archaic (10 000–4000 BCE). Predilection for certain areas, some authors suggest, derived in their population and subsequent emergence of sedentary occupations, privileging some parts of the Central Andes as well as certain sections of the Pacific coast.

The Andes

Given its large and diverse geography and social characteristics, it is difficult to frame the past of the Andes within a few specific topics without neglecting others. However, considering the variety of ecological and sociopolitical scenarios, the different forms of interaction between and within the peoples that populated this area need to be highlighted. Whereas conflict, warfare, and competition are crucial to many models of social interaction (*see* Conflict and War, Archaeology of: Behavior and Social Organization), the widespread networks established within and throughout the different regions of the Andes and further through time constitute the most important theme in South American archaeology. These concepts relate to a wide spectrum of social interaction among Andean societies as key elements in explaining the relationships between Andean societies; additionally, they present a powerful model incorporating aspects such as mobility and social organization of early archaic groups of the South Central part of the Andes, which prevailed until later periods (Murra, 1985; Nuñez and Dillehay, 1995). The connections and patterns of mobility between these different regions developed widespread networks of interaction and established the foundations for what would be called ecological complementarity (Murra, 1985).

Closely related to complementarity is the debate about the origins of Andean civilizations. This debate unfolded early in the twentieth century and involved the Harvard-educated Peruvian Julio C. Tello who would be known later as the father of Peruvian archaeology, whose autochthonous theory countered Max Uhle's theory of external origins. Tello proposed that Chavín de Huantar, an archaeological site located in the Peruvian *sierra*, was the 'mother culture' of Andean civilizations. He considered the evidence of monumental architecture and iconography at Chavín de Huantar to be related to a strong religious and sociopolitical structure of a society that began in the Amazon Basin, and evolved in the highlands to become the progenitor of civilizations. On the other hand, taking a diffusionist standpoint, Uhle postulated that the Andean civilizations were the result of migration from Mesoamerica and, hence, had their center in coastal areas. Not only was this debate related to the culture historical efforts of chronology building that characterized archaeology at the time, but it was also related to an ideological and theoretical controversy deeply inserted at the heart of South American archaeology.

Thus, for example, subsequent works in the Ucayali Basin (Lathrap, 1977) and at Chavín (Burger, 1992) were taken vis-á-vis Michael Moseley's *Maritime Foundations of Andean Civilizations* (1974). Both groups of theories took a materialistic point of view related to economic factors and means of subsistence. While those in favor of the origins in the highlands argued for the importance of agriculture and the domestication of animal species, mainly camelids, and the importance of interregional interaction between *sierras* and lowlands, those who favored the coastal origins highlighted the importance of marine resources, without precluding the practice of farming. In support of coastal origins, scholars cited evidence of cultigens such as beans, squash, and cotton that was found associated with artifacts of fishing technology in several excavations at sites on the Pacific littoral.

To the south, Wendell C. Bennett commenced research at Tiwanaku with sponsorship from the American Museum of Natural History. This monumental site in the Bolivian highlands near Lake Titicaca had been reported before by prehistorians like Bandelier, Stübel, and others who visited the region, following early colonial accounts. Uhle's earlier observations on stylistic sculptures and architecture provided him enough information to argue that Tiwanaku predated the Incas. Bennett's attention was centered in the monumental architecture of the site and other religious manifestations. He correlated and complemented his architectural data with an analysis of the style of ceramic decorations recovered from his excavations, establishing a chronological framework for the site. These chronological sequences and debates gave shape to the chronology of Andean pre-Hispanic societies.

Attempting to provide a chronological backbone accountable for stylistic and technological changes, John H. Rowe criticized previous chronological frameworks as inadequate to explain the origins and diffusion of archaeological traits. Based on his work in Ica Valley, Rowe proposed a pottery seriation sequence of horizons and periods, as units of time that could be used to correlate the most important events within different parts of the Andes (Rowe, 1962). Rowe's sequence was not initially based on absolute dating methods; it was Edward Lanning (1967) who later complemented and adjusted the initial sequence to the information provided by radiocarbon dates (*see* Chronology, Stratigraphy, and Dating Methods in Archaeology). Although archaeological research in other areas and sites soon posed a series of challenges for these initial proposed sequences, the three main units of this sequence (the Early, Middle, and Late periods) remain the chronological backbone of Andean archaeology. Each unit is related to major cultural traits widespread through different regions of the Andes, implying evolutionary stages of social development.

The Early period is commonly linked to early hunter-gatherer societies, and is derived in large part from lithic technologies and a few examples of pristine architecture (Osorio et al., 2011; Shady et al., 2001). Production activities at the end of this period include permanent occupation and inhabitation of sites that led to less mobile lifestyles as well as technological innovations like ceramic and agricultural production, complementing pastoral and herding activities. Archaeologists have also scrutinized the processes of animal and plant domestication, which occurred as early as 8000 BCE in parts of the Andes, according to evidence of domesticated squash and maize at sites such as Las Vegas, Real Alto, and Loma Alta, in Ecuador. Although maize was adopted a bit later (5000 BCE), maize was ubiquitous at Real Alto by 2800–2400 BCE, along with achira, manioc, and some tubers. Similarly, evidence of arrowroot was reported in the Cauca Valley, Colombia. Parallel to developments in northern South America, the Andean highlands present solid evidence for the presence of contemporaneous plant domestication. In the Titicaca Basin, domestication of quinoa and other species had taken place by around 800 BCE (Bruno and Whitehead, 2003). Use of these plants was associated with an increased use of hoes, farming communities, and with the emergence of social complexity during the Formative period. Similarly, the domestication of llamas and alpacas around 5500 BCE contributed to the development of Andean society by providing a means of transporting goods as well as raw material for the manufacture of textiles, a significant commodity. New methodological procedures have built on earlier contributions on plant domestication and of incorporation of animals into consumption and ritual practices in earlier societies, providing wider frameworks of interpretation (DeFrance, 2006; Perry et al., 2007).

Whereas the domestication of animals and plants was an important aspect of this period, another has to do with gradual intensification related to agricultural production, technology, and political organization. Different kinds of earthworks were constructed to improve the conditions of or expand the capacity for food production and storage through different configurations of labor mobilization. Irrigation canals, for instance, were used to provide water to extensive areas of the northern Andes, especially in desert settings. Raised fields, generally built in swampy areas (Denevan, 2003), provided areas for cultivation and avoided seasonal or temporary floods by elevating agricultural surfaces. Other settings, like the steep and narrow valleys of the intermontane region, also show massive pre-Columbian terrace construction (Niles, 1999). These constructions provide evidence for a large and sustained modification of the natural landscape, and modified the climate by creating a humid warming effect to protect crops from low temperatures. Because of the magnitude and technological sophistication, most of these constructions – as was the case with raised fields and terraces – were associated with intensive agriculture and stronger economic strategies that involved investment in and administration of a massive work force. The estimated size of these work forces has been suggested as a correlate for social complexity (Kolata et al., 2000). However, drawing from experimental archaeology research in southern Peru, Erickson (1999) suggests that earthworks such as check dams, cross channels, sloping field terracing, and others could be the result of the work of domestic units without the need of hierarchically organized labor.

The Middle period includes both the so-called formative societies (Pucara, Chavín, Moche, others) and state societies (Tiwanaku, Chimu, Paracas, others). The former are characterized by the construction of public spaces, sunken temples, and incipient farming, the latter represent socially and politically consolidated societies. A significant feature of these state societies is a shared religious ideology that gradually became institutionalized. These shared ideologies were preceded by the Kotosh tradition in Chavín (Burger, 1992) and the Yaya Mama tradition in societies of the circum-Titicaca region. The importance of religious traditions has been proposed mainly from evidence found in emblematic sites such as Chavín de Huantar, Huari, Tiwanaku, Pachacamac, and various Moche sites. The monumental architecture found in these sites (Moore, 1996) can be related to former small villages of permanent residence and earlier religious centers. The importance placed on the religious and economic influence of societies such as Chavín, Tiwanaku, and Huari, which is manifested through a broad set of interregional networks connecting administrative and religious centers with hinterland regions, has privileged the South Central Andes as the cradle of Andean civilizations.

Evidence suggests that early settlements in other parts of the Andean coast, such as Real Alto and Las Vegas in Ecuador and

Las Haldas, Aspero, and Caral in Perú (Shady et al., 2001), could have had similar and parallel developments leading to early forms of urbanism. The consolidation of these processes gave rise to well-established societies characterized by complex social structures and institutions, and makes necessary an intricate scenario of interrelationships among regions in the Andes, the coast, and the Amazon.

One of the most representative characteristics of the Middle period is the strengthening of the exchange and interaction networks that articulated around some capital cities such as Tiwanaku (Kolata et al., 2000) located in the south-central Andes, the circum-Titicaca region or Pachacamac and Conchapata (Isbell, 2008) located in the northern Andes, which bound widespread regions. According to Isbell, these cities epitomized social formations with state government, well-defined hierarchical social structures, and an ample sphere of interactional dynamics. Characterized as a ritual, civic, and political center with the presence of monumental architecture, Tiwanaku is said to have covered an extensive area of the southern Andes, comprising the Bolivian *altiplano*, northern Chile, and northwestern Argentina, through its relationships of economic interaction. On the other hand, Huari, along with sites like Conchopata located at the *sierra*, is said to have expanded its domains to incorporate the coastal areas of present-day Peru. Architectural features like orthogonal compounds found in Pachacamac and other coastal sites suggest a strong, although not conclusive, relationship. A little further north of the Moche, another social entity seems to have been part of a complex relationship with the rest of the complex scenario during this period (Chapdelaine, 2011). Monumental sites such as Huaca de la Luna, Chan Chan, and others provide evidence of a complex development of social and political nature in this part of the Andes.

The Late period is characterized by the Inca state (D'Altroy, 2002) and its administrative control over a broad territory of the Andes sweeping from the present south of Colombia to the central Chilean valley of Aconcagua. According to traditional chronological schema, the Incas represent the most advanced stage of evolution of Andean societies prior to the arrival of the Spanish conquerors. Centered in Cuzco, the Incas had expanded their territory through a variety of strategies, annexing territory through violent domination or political persuasion. The diverse scenarios that the Inca occupation produced in the already complex sociopolitical landscape of the Andes characterize this period. The presence of the Incas left a distinctive imprint in the Andean landscape; many of their administrative centers are clearly recognizable by their architectural features, which follow the construction patterns of the capital city.

Archaeological evidence found in these administrative centers suggests that the Inca developed previously unseen systems of colonial control over the conquered territories. This was done through a complex and gradual process, mostly between AD 1000 and AD 1400, that involved such strategies as the uprooting of certain groups who served to establish new colonies of *mitmaes* or *mitmaquna* and were put in charge of conducting military, economic, and political or administrative tasks for the Inca ruler (Acuto, 2005). As the state attained more political power over conquered hinterland territories and grew demographically, it was necessary to reinforce previously existing production technologies like terraces and irrigation systems. These were sometimes combined with ideological and religious systems like the lines of shrines called *ceques* (Kolata, 2013). The Inca also developed mechanisms of social control, which included violent forms of suppression (Conrad and Demarest, 1990) as well as political enticement and alliances to attain voluntary submission. In many cases conflict characterized the relationships with local groups (Ogburn, 2007). By the early sixteenth century, when the Incas had achieved control over a vast territory, the Spanish conquest took place.

The Spanish conquest produced a cataclysm in the structure of Andean societies as the Spanish seized political and administrative power from the Incas and transformed Inca authority into what became the colonial system. Part of this new system included the *encomienda*: a concession of territory along with its population for the administration of the *encomendero* or feudal lord that resulted in quick amassing of fortune by the conquerors at the expense of the native population's peonage labor. Much of the debate concerning this period has been based on the chronicles and historic colonial documents; whereas, on the one hand, the information of colonial provenance has been a valuable source of information, on the other, it has been highly criticized for its ethnocentric perspective and bias against the colonized societies. Although some scholars have explored diverse aspects related to this period in the Andes such as mining, production, and consumption practices and architecture of early colonial cities, the colonial period has largely been overlooked by archaeologists and considered the domain of historians (Van Buren, 2010). This is in stark contrast with the Caribbean and Brazil, for example, where archaeological contributions to historical and colonial period research have delved in to issues like ethnicity and ethnic relations, slavery, and racial tensions in colonial societies (Funari and Britez, 2006). However, as different recent contributions emerging mainly in the last decades have shown, there seems to be an increasing interest in this period.

The Amazon

The Amazon has never seen the same intensity of archaeological research as the Andes. During the late nineteenth century, while explorers were documenting the cities, monuments, and arts of the Andes, at the mouth of the Amazon the spectacular art of the Marajoara was rediscovered (Schaan, 2012). However, the momentum of these initial efforts was not sustained and by the middle of the twentieth century, Amazonian archaeology was a very small field, dominated by fundamental disagreements about the archaeological record and its interpretation. Only in the early twenty-first century could the Amazon be thought of as having a mature and growing community of scholars, focusing on several problems from a variety of theoretical vantage points (Heckenberger and Neves, 2009). One recent summary (Stahl, 2004) called on archaeologists to raise their expectations with regard to the cultural achievements of pre-Columbian Amazonians. Archaeological study of pre-Columbian peoples changed our understanding of the ecology and natural history of the region. South America, and the Amazon in particular, represents the 'wilderness,' and the opposite of civilization. The Amazon

remains an important foil to the Old World of cities, post-industrial civilization, and modernity.

What archaeology adds is an increased and increasing understanding that this mythical wilderness has not only been inhabited for millennia (Erickson, 2006), but that the occupation changed the wilderness in lasting ways. Today, as forests are cleared, earthworks emerge in western Brazil, showing that the timeless forest has a definable history (Schaan, 2012). The connection between the artificial soils studied by soil scientists, and the occupation middens studied by archaeologists shows that large sedentary populations lined Amazonian rivers (Lehmann, 2003). To conserve the Amazon Basin because it is the last untouched wilderness denies the history and the humanity of the generations of Amazonians who farmed and fished, trekked, and hunted there. A more accurate understanding is to analyze the Amazon as a product of human society in relationships with water, fire, earth, trees, crops, weeds, fish, animals, and birds.

How can we use archaeology to better understand the Amazon without creating another myth? Keeping archaeology in conversation with many stakeholders, including indigenous Amazonians and other South Americans, should provide some protection. The more public and connected archaeological knowledge becomes, the harder it is for anyone to control. Today archaeologists are finding a wide range of evidence, which is changing our understanding of American archaeology more generally.

Ceramics are a powerful technology that demonstrates knowledge of materials and mastery of pyrotechnology. The earliest ceramics in the New World were created and used in the Amazon at Pedra Pintada, about 7500 years ago (Roosevelt et al., 1991). In the context of this significant development in technology, the Amazon does not suffer by comparison with other parts of the Americas. The choices potters make as they shape and decorate their pots express a huge range of cultural ideas. And after the pots are made, people use them to cook and conserve their food, bury their dead, and demonstrate and create their social status. Schaan (2012) analyzes ceramic 'tangas' as part of rituals associated with female initiation. The use of ceramic vessels as burial urns gives insight into indigenous ideas and behaviors about death. Ceramics are also at the center of modeling the movements of societies over the long term throughout the Amazon Basin (Neves, 2008; Hornborg, 2005).

Modification of the soil and control of water to improve conditions for agriculture was once studied as one of the prime movers of the rise of political complexity, the state, and civilization. Although this question no longer has the same urgency, the creation of landscapes of intensive agriculture is significant because it corresponds with the investment of labor in the landscape, increased agricultural potential, and the organization of that labor. Since the 1960s, it has become apparent that South America is literally covered with systems of pre-Columbian intensive agriculture (Denevan, 2003). Archaeologists are studying more of these systems, and new examples are emerging as satellite imagery becomes more widely available (Rostain, 2008). Not the least important implication of this part of the archaeological record is that some of these systems of intensive agriculture were sustained over at least several centuries. The archaeological record from Marajo Island documents the development of an art style and tradition on a par with those of more widely recognized societies in the Americas (Schaan, 2012). It also documents how nonstate societies controlled flows of water to engineer the environment.

One of the most important markers in the archaeological record is the city. Cities are the most complex artifacts created by humans. They are large, complex transformations of the environment which move humans away from their original connections to the environment into second and third order relationships. In these artificial places, new ideas about politics, economics, religion, art, and technology are incubated. Before the past few decades, no one would even have suggested that cities could have been part of the Amazonian archaeological record. Although it is a minority position, Heckenberger et al. (2008) describe a collection of large circular occupation sites in the Xingu as forming a network similar in scope and size to the cities that emerged in the early middle ages in Europe. These settlements were almost certainly not the products of a strong central power, but they could be the expression of a dynamic process that also included linguistic and cultural diversity, and novel forms of social organization. As a counterpoint to the precocious societies of the north coast of Peru, evidence of ceremonial architecture and sophisticated art from the fourth millennium BC has recently been discovered in the Ecuadorean Alta Amazonía (Valdez, 2013). Ceramics, domesticated plants, intensive agriculture, and urbanism are crucial in the deep history of civilization, and of Amazonia.

The archaeological record of the Amazon includes evidence regarding three points of general interest. First, it seems that the 'natural' environment of the Amazon is riddled with evidence that humans modified and manipulated plants, animals, and landscapes in ways that dissolve any easy contrast between nature and culture (Erickson and Balée, 2006). This is not to say that the Amazon is in every way an artificial construction, but instead something more fundamental. As is suggested by ethnographic accounts about how indigenous people think about nature and culture, these anthropogenic environments were built by communities that may have had very different ideas about how people relate to nature. For some Amazonians, trees and mounds are social beings, with whom one can and must interact, and this would suggest that different actions are appropriate (Dillehay, 2006). Animals are also in some cases thought of as ancestors. Pre-Columbian Amazonians did not separate nature and culture in the same way as Western science (Descola, 2013). Following the trajectory of such communities and such societies through deep history would seem to be of great utility as we make policy decisions about relationships between humans, technology, and resources.

Conclusion

One point of view says that South America is unique and independent of traditions in other parts of the world, one of the independent hearths of civilization. As civilization is defined more broadly and evidence of human achievement over very long periods of time accumulates, it would be foolish to imagine any place where humans had settled as being truly derivative from anywhere else. In South America, research has focused first on the Andes, and only in more recent decades on

the Amazon. The archaeological record suggests that pre-Columbian peoples did not observe such a strong division between these domains. The combination of the Andes Mountains with tropical latitude means that a wide range of environments are within easy reach of people on foot. Farmers, herders, and traders moved up and down the mountains, from coastal deserts and valleys up past the snowy peaks down to the forests, and savannas on the other side. The differences between these environments contributed to tremendous diversity in economy, culture, and politics. The movements of people, goods, and ideas up and down the mountains collapse any simple dichotomy between the highlands and the lowlands, between the Andes and the Amazon. The future of archaeology in the Amazon is sure to include interaction with Andean archaeology, but also closer integration with anthropology and tropical ecology, as the archaeological record becomes part of larger understandings of the Amazon Basin.

At the turn of the twenty-first century, archaeology in South America has undergone significant changes. In the Andes as well as in the Amazon, long-standing topics have remained central, such as early peopling, formation of state societies, and technological responses to environmental adaptation (Lombardo et al., 2013; Osorio et al., 2011; Roosevelt et al., 1991). A combination of residue analysis on artifacts and other techniques such as pollen and phytolith analysis has been instrumental in identifying and dating processes of domestication and use of different species of crops and plants in the past. The application of archaeometric technologies to fine tune chronological charts (Steele and Politis, 2009) and innovative nondestructive techniques have been employed to explore issues like compositions of metals and provenance of metal objects (Lechtman and Macfarlane, 2005) as well as obsidian and other resources commonly found in archaeological contexts (Yacobaccio and Morales, 2005). Many of these new techniques have been applied to address old questions (trade and exchange, ideological use of objects and raw materials, peopling of the Americas).

Theoretically, with the advent of changes in the field during the last decades of the twentieth century, Latin American archaeologists have also departed from traditional frameworks and incorporated different theoretical approaches to problem-oriented research (Politis, 2003). Although this is an ongoing process, recent work is also characterized by interest in landscape (Walker, 2012), agency, and the politics involved in archaeological knowledge production. The development of national and regional archaeologies, which once gave the discipline its foundational core, has been fruitfully criticized. Recent contributions from Latin American scholars have emphasized the need to scrutinize the relationships between archaeology and society, reflected mainly in the sociopolitical contexts of the different countries (Angelo, 2011; Benavides, 2004). As part of this, issues of representation and domination regarding identity, ethnicity, and nationalism have been examined along with issues of heritage and the situation of indigenous communities in relation to national cultural politics. Another new issue related to the recent past of the South American countries comes from the Dirty War period, developed mainly in Argentina, where archaeologists and forensic anthropologists have painstakingly recovered evidence to bring to justice those responsible for the case of the disappeared during the military dictatorship (Funari and Zarankin, 2006). As archaeology becomes more global, the themes of South American archaeology expand the theoretical, methodological, and political scope of our understanding of the past.

South America: Sociocultural Aspects

Norman E Whitten, Jr., University of Illinois at Urbana-Champaign, IL, USA

Abstract

Native South American cultures prior to 1492 represented a dynamic mosaic of languages, cultures, social systems, rituals, and power relationships. Long-distance trade – sometimes extending for thousands of miles – combined with bilingualism and multiculturality. By the creation of an empire through conquest, the Inca altered the cultural mosaic in the Andes in the fifteenth century. A new cultural system was violently created by the overseas Spanish and Portuguese empires after 1492 in their conquest and radical colonization of the continent. The Spanish and Portuguese brought black slaves from Africa and from Iberia with them. Many such people escaped to create free, fortified sites where Native American and African American people often collaborated, intermarried, and established political systems on the fringe of the dominant colonial territories. The Spanish initiated an ideology of ethnic blending, called *el mestizaje* ('the blending,' or miscegenation). In the late twentieth century, indigenous and black movements in South America worked against this false imagery and misleading ideology of ethnic blending in their respective nation-states and across national boundaries. Cultural diversification and nationalist centralization characterized the South American nation-states in the late twentieth century as they did during colonial and republican epochs. Such centripetal–centrifugal forces are seen in cultural performances and in social movements.

South America, the world's fourth largest continent, is composed of 12 nation-states and 1 territory. The significant differences among these 13 countries are matched by great internal sociocultural and ethnic diversity. Contemporary neoliberal and authoritarian governments strive to centralize and homogenize their populations. Internal cultural, social, and political movements heighten diversity and conflict. The military often plays a strong role in centralizing efforts. In the past decade, new forms of socialism have emerged in some nations that both challenge neoliberalism and at the same time seek to use it creatively for social reforms. The Roman Catholicism of European colonialism historically and culturally shapes the pan-national and internal cultural unity of the 10 Iberian-derived nations. Diversity is especially strengthened by the striking polarization between the small wealthy minority and the large poor majority; by indigenous and Afro-Latin American movements of cultural and ethnic self-affirmation; by the presence of significant ethnic blocs resulting from European migrations since the two World Wars; by the struggles among leftist, rightist, and populist political parties; by the challenge of the twentieth- and twenty-first-century spread of Protestantism; and by the liberal Catholicism of recent reforms.

Human and Topographic Diversity

South America's rapidly expanding population contains as wide a spectrum of phenotypic features as found anywhere in the world (e.g., Collier et al., 1985; Fuentes, 1992). Its modern nation-states are Venezuela, Colombia, Ecuador, Peru, Bolivia, Chile, Uruguay, Paraguay, and Argentina, where Spanish is the official language; Brazil, where Portuguese dominates; Guyana, where English is the national language; Suriname, where English, Dutch, and Sranan are prevalent; and Guyane, an administrative district (*département*) of France, where French is dominant. Quechua is also an official language of Bolivia, Peru, and Ecuador (Quichua), as is Guaraní in Paraguay. A myriad of other languages are spoken in most of these countries.

Western South America is dominated by the mighty Andes mountains, with snow-coned active volcanoes that rise to 20 000 feet. They extend southward from the Caribbean Island of Trinidad to terminate in southern Argentina at Tierra del Fuego. In this region, Venezuela, Colombia, and Ecuador are known as the northern Andes (and the former two as the Spanish Main); Peru and Bolivia constitute the central Andes; and Chile, Paraguay, Uruguay, and Argentina are called the 'southern cone.' Eastern South America features the great Amazon Basin, epitomized by the Amazon itself, the 'Ocean Sea.' Toward the headwaters of the huge feeder rivers of the Amazon lie the mountainous Guiana Shield in the north, the Brazilian Shield in the south, and the Andean foothills or *montaña*, rimmed by the *ceja* ('eyebrow') in the west. Northwest and northeast of the Amazon regions, and west of the Guiana Shield, are the plains (*llanos*) of Colombia and Venezuela, which phase into the Orinoco Basin, and west of the Brazilian Shield are the *llanos de Mojos* of Bolivia. A subregion that combines elements of Amazonian and Andean systems is the North Pacific coast. From northern Ecuador through western Panama, an Amazonian ecosystem prevails. From northern Peru southward, high aridity is characteristic (e.g., Collier et al., 1985).

Pre-Columbian People: Their Lands, Products, Societies, and Languages

Native South American cultures prior to 1492 represented a dynamic mosaic of languages, cultures, social systems, rituals, and power relationships (Denevan, 1976; Dillehay, 2000; Hornborg and Hill, 2011; Silverman and Isbell, 2008). Long-distance trade – sometimes extending for thousands of miles – combined with bilingualism, or multilingualism, and multiculturality. Such trade traversed some of the most rugged landscapes in the world, creating networks of native knowledge and imagery crosscutting great geographical differences. The antiquity of South American native peoples is highly controversial. In the east, and thence up the Amazon and Orinoco (the latter has its headwaters in the Parima and Pacarima

mountains of the Guiana Shield and flows west, then north, then east out into the Atlantic), evidence suggests antiquity of 12 000 years ago or earlier, but the routes of arrival are obscure (e.g., Dillehay, 2000). Neither transatlantic nor transpacific routes seemed credible to scholars in 1999, although sporadic contacts in South America by the first Americans with Asian-Pacific and Euro-African peoples remain subjects of possibility, discussed in the early twenty-first century. Plant domestication seems to have begun in Amazonia and in the Andes by about 8000 years ago. Interactions between Andean and Amazonian people are demonstrated by literature in the twenty-first century to be more common than previously thought (Hornborg and Hill, 2011; Silverman and Isbell, 2008).

The period beginning about 6000 years ago and continuing until the European conquest and colonization marks the florescence of fine ceramics in greater Amazonia, and the development of textiles, gold work, and silver work in the Andes and adjacent coastal regions. Pottery may have had its origin in the Upper Madeira basin near the border of Brazil and Bolivia; later, it is found in abundance at the mouth of the Amazon and subsequently along the banks of the Amazon. Ceramics manufactured on Marajó Island, an area the size of Connecticut in the United States, rivaled the quality of any ceramic wares found anywhere in the world in terms of their beauty of form and decoration (Hornborg and Hill, 2011).

By 4500 years ago, great westward migrations from the lower and central Amazon region were underway, and regional consolidation in the Andes was occurring. People from coastal, Andean, and Amazonian regions were in contact with one another, and with the people of the Caribbean Islands, Central America, and Mesoamerica. People who belong to three language families – Arawak, Carib, and later Tupi – spread from the eastern and central Amazon to the Orinoco drainage and on to the Caribbean (Arawak), and to the base along the rim of the *montaña*. Other Amazonian language families of prominence include Tukano, Tukuna, Jívaro, Pano, and Gê; these languages spread in a general arc from northwest of the Amazon around the central Amazonian rim to the southwest. Andean languages were also highly diverse. Quechua, a dialect of which was adopted by the Inca, has a known time depth of only 1000 years; scholars are still teasing out earlier linguistic diversity in the Central Andes.

The Inca Empire, radiating north and south out of its capital of Cuzco, in what is now Andean Peru, emerged in the fifteenth century to severely alter the cultural mosaic in the Andes, and set up political-economic and cultural shock waves that radiated eastward. This empire was in full conquest fervor and bureaucratic consolidation by the time that word arrived from the Caribbean and Central America of the pending Spanish advances down the Pacific Coast and up into the Andes. At the height of their expansion, the Inca controlled all Andean systems from central Chile to southern Colombia, and their north-south 3416-mile parallel cobblestone roadway (one coastal, one Andean) through this vast territory (385 000 square miles) amazed the conquering Spaniards. Although the Inca never dominated the adjacent indigenous people of Upper Amazonia, there is ample evidence of extensive trade and cultural exchange between Amazonia and the Inca-dominated Andes and coast (Richardson, 1994). A dialect of Peripheral Quechua (which is related to Quichua) was the lingua franca used by the Inca in its conquest, and Quechua became the language of millions of people throughout the empire and beyond (Whitten and Whitten, 2011). Other prominent Andean languages include Barbacoan and Chocoan in the northwest coastal region, Chibcha in the north Andes, Aymara in the central Andes, and Mapuche in the southern cone.

In the greater Amazonian areas east of the Andes, people depended on maize, manioc, a variety of root crops, and palm cultivation for caloric intake, and on intensive fishing and reptile and amphibian collecting for protein and amino acid balance. Hunting in the various ecosystems of the flooded forest, the upland forest, and the flood plains and riverine systems complemented the balance of fishing and horticulture. As time progressed, manioc (*Manihot esculenta* Crantz), which, like pottery, probably had its origins in the Upper Madeira basin (Hornborg and Hill, 2011), came to be the staple of the agricultural system, with maize sporadically and regionally grown and consumed. Use of palms was and is ubiquitous. Fishing in rivers, estuaries, streams, and coastal waters was of paramount importance, as were techniques for corralling turtles and other amphibians. Polities varied from well-developed chiefdoms and relatively small-scale states to more dispersed systems. Intermarriage between peoples at war with one another, and speaking different languages, seems fairly common.

In the Andean regions, the potato was the supreme crop, with beans, squash, maize, quinoa, and other grains providing a balanced diet when combined with animal protein. Approximately 240 species of potato were grown, harvested, and prepared in many ways. The llama (one of three Andean camilids), the guinea pig, and later the hairless dog were the primary animals raised for food, and the llama was also used as a beast of burden. Polities ranged from small-scale systems to states and the expansive Inca Empire (Richardson, 1994).

The European Conquest of Native Lands and People

A new cultural system based on conquest and capitalism was violently created by the overseas empires of the Spanish and Portuguese after 1492 as they sought huge profits in gold, silver, spices, and slaves. In the Treaty of Tordesillas, signed in 1494, the Spanish and the Portuguese divided up their colonies long before they knew the vast extent of their respective territorial 'holdings.' From the terms of this treaty, the Portuguese would lay claim to Brazil, and Spain would take the rest, including all of the Pacific regions from South America to the Philippines and Japan, all of the Andes, and a part of Amazonia, a territory itself nearly the size of the United States. Portugal's interests first lay in the route around the horn of Africa to India, and only a bit later in its vast new colonies (e.g., Goodman, 1992; Williams and Lewis, 1993). In 1499, while sailing (and/or writing) for Spain, Amerigo Vespucci signed his map of the 'New World,' thereby creating the currently favored name for the entire continent (America). During the early to mid-1500s, Spain set out to locate, conquer, and colonize its Amazonian, Andean, and coastal regions, and Brazil set out on the conquest of its Amazonian, coastal,

and mountainous regions. The Spanish first brought sugar to the Americas, and the Portuguese first brought the banana from India. Both of these overseas empires introduced cattle, sheep, goats, pigs, and chickens.

Everywhere they went, the conquerors encountered native people. They subdued them by enslavement, trickery, and trade, and they spread European and African diseases for which native resistance was low or nonexistent. Where possible they enlisted them in slaving activities, and they killed indigenous people with firearms, swords, spears, and arrows with steel points. In areas feasible for such warfare they sent their war horses and war dogs to maim and kill native people in their radical colonization of the continent (Hall, 2005; Varner and Varner, 1983). This brutal transformation resulted in 90% or greater depopulation of the native inhabitants throughout the continent (Denevan, 1976). Trade and warfare, now with an escalating colonial need for indigenous chattel slaves in the lowlands, and indigenous landed slaves in the highlands, created a persistent poverty that endures into the twenty-first century. Nonetheless, cultural creativity endured with local-level technical competence to promote subsistence and adaptations (e.g., Van Cott, 1995).

Blackness

The Spanish and Portuguese brought black slaves from Africa and from Iberia with them (Bryant et al., 2012). Many such people escaped to mountainous, forested, inaccessible areas, and created a myriad of free, fortified sites where Native American and African American people often collaborated, intermarried, and established powerful political systems on the fringe of the dominant Spanish and Portuguese territories. From these refuge sites, often called *palenques* in Spanish and *quilombos* in Portuguese, self-liberated residents established powerful political systems on the fringe of the dominant Iberian and colonial territories (Price, 1996; Redstall, 2005; Whitten and Torres, 1998). They threatened the Crown political economies. In some regions such as western Ecuador, southwestern Colombia, western Venezuela, and the north of Brazil, active trade between runaway people, often called *cimarrones*, and the colonial planters ensued. There was also movement among free black people between Africa, Iberia, and the Americas.

Mestizaje, Cultural Practices, and Ideologies of Racial Blending

The Spanish initiated an ideology of ethnic blending called *el mestizaje* ('the blending,' or miscegenation) that excluded both indigenous people and people of African descent. Spanish administrators from the Republic of Spaniards demarcated a Republic of Indians (or '*indios*'), so named by Christopher Columbus, who thought he was in India. There was no legal space for black people, except what they themselves created. Those excluded from the Spanish-Mestizaje realm were sometimes referred to as *la mancha*, 'the (racial) stain.' From this viewpoint, the dominant, European concept of hybridity prevailed in this hegemonic model of racial mixing: the white, civilizing genes and cultures were to mix with the savage or barbarian 'Indian' and 'black' to form such intermediate categories as *mestizo* and *mulato* in Spanish. In Portuguese, *mestiço* and *mulato* referred to white–black hybridity (Whitten and Torres, 1998; Whitten and Whitten, 2011).

Those people with hybridized 'racial' features, according to European and later Creole (New World born) ideologues, ranged up and down the scale from white civilized Iberian to dark civilizing Creole. People in the diverse *mestizo* category were known in many areas as constituting the *castas*. In some times in some places, the number of their racialized categories ranged from a dozen named 'types' to hundreds. Indeed, there could be five or more such 'types' among the sons and daughters of one couple. They were constituted as those people somewhere betwixt and between the savage and the civilized, and legal and colloquial labels for some of them included such racialized concepts as 'wolf,' 'coyote,' 'throw back,' 'up in the air,' and even 'there you are!' Translation of 'casta' as 'caste' is erroneous.

Black people (including slave, '*bozal*,' and free, '*ladino*') and native people (usually divided into tame, '*manso*,' and fierce or wild, '*bravo*') fell outside of the scheme of *castas*. Their own intermixture, often rendered in Spanish by the term *zambo*, was (and is) a category filled with racist ideas about danger and power, for here was a mixture without the civilizing effects of European-sponsored hybridity. Such people were sometimes called 'the Devil's mix' by the white and powerful (Redstall, 2005; Whitten and Whitten, 2011). An indigenous artist using European techniques in 1599 did the first oil painting in South America. His subject was the 'Zambos' of western Ecuador who, adorned in European princely clothes, wearing indigenous gold jewelry, and carrying spears with iron tips characteristic of Africa and Europe, walked 100 miles from their free Zambo Republic on the coast of Ecuador to Quito to swear alliance to the Spanish Crown in the face of English encroachments (Whitten and Whitten, 2011).

Before the rise of nation-states, movements of self-liberation by black people and indigenous people were common, and some were quite successful. Early revolts in the sixteenth century resulted in ethnic regions that endured into the era of nation-state emergence. In 1579, the Quijo and the Jívaro of the Ecuadorian *montaña* revolted in attempts to unite Amazonian and Andean people (Uzendoski and Calapucha-Tapuy, 2012; Whitten and Whitten, 2011). In Peru and Bolivia, the revolts of Tupac Amaru and Tupac Katari later did the same. In the forested and mountainous coastal zone of Alagoas, Pernambuco, Brazil, black and indigenous people formed the state of Palmares in the 1640s, and they fought Portuguese and Dutch soldiers for a century (Redstall, 2005). Black people in Suriname revolted in the mid-seventeenth century, and initiated a 100-year war against the Dutch and British, winning independence for six nations – Saramaka, Paramaka, Kwinti, Ndujka, Matawai, and Aluku – in the interior of this region (Price, 1996). In neighboring Venezuela, the Carib-speaking Yekuana expelled the Spanish in 1767, and maintained their complete independence for 100 years until a brutal nationalist regime militarized the area for the purposes of exploiting wild rubber (Guss, 1999).

The Transformation from Colonies to Nation-States

Wars of nationalist independence from Spanish and Portuguese colonial rule began in 1810 in areas of vast distances from one another, from what is now Mexico through northern South America to the southern cone. Those who achieved positions at the pinnacle of power in South America were *criollos*, 'Creoles,' who outnumbered those of Spanish descent. In turn, they were vastly outnumbered by their darker compatriots, especially those of African descent who fought in wars led by Simón Bolívar in the north, and by José San Martín in the south. As the Creole nationalist wars moved through slave territories, slavery was abolished, but blackness and indigenousness were kept under rigid control by fears that the revolution would become an 'ethnic' one. The ethnically marginalized continued to be excluded from dominions of power. Both Bolívar and San Martín envisioned a united Spanish-speaking Creole nation, and lightness of phenotype within the ideology of *el mestizaje* was clearly ascendant (Anderson, 1991; Stern, 1987; Whitten and Torres, 1998).

Such a continental nation did not materialize and, one by one, contemporary nation-states rapidly emerged from their previously liberated colonial regimes. By 1822, Spain had lost all of its territories in the Americas, and the Portuguese king lost his colony to a new Brazilian monarchy with its own New World Empire. By 1830, all of the republics of Spanish-speaking South America had emerged, only to begin border wars, geopolitical vestiges of which last to the present day. Peru, for example, invaded Ecuador in 1941, claiming half the latter's territory, and these countries fought a war over a very small sector of disputed territory as recently as 1981 and 1995, both of them in indigenous Jivaroan-occupied sectors long serving as refuge areas due to the rugged, mountainous, Upper Amazonian topography (Whitten and Whitten, 2011).

African chattel slavery continued in the new states side by side with black freedom, as various systems of oppression of indigenous people continued side by side with native revolts (Escobar, 2008; McKnight and Garofalo, 2009; Silverblatt, 2004). The last country to abolish slavery, Brazil, did not do so until 1888, and in some states illegal slavery existed side by side with manumission legalities. Not until 1966 (Guyana) and 1975 (Suriname) would two of the three Guianas gain nation status from the British and the Dutch, respectively.

The Fusion of Cultures

The powers of Spanish and Portuguese Catholicism came to South America in the heyday of the Spanish Inquisition (Silverblatt, 2004; Whitten and Torres, 1998). Powerful priests and others sought out indigenous and African systems of thought and knowledge to be stigmatized as idolatry and devil worship. An underlying fear of converted Jews permeated some middle ranks of conquest and colonialism. The Inquisition became known through history by different names and is now (2013) the Vatican's Congregation for the Doctrine of the Faith, once headed by Cardinal Joseph Ratzinger who went on to become Pope Benedict XVI.

Those of humble Iberian origin sought alternative sources of inspiration for religion and magic from indigenous and Black people, thereby heightening the symbolic powers of the oppressed. Fusions of Iberian, African, and indigenous belief systems and ways of knowing and 'seeing' became legion. All this occurred at microlevels in macrosystems of Iberian Catholic missionization that give almost all of South America its special 'Latin American' sociocultural character (Ades, 1989; Collier et al., 1985).

In the area of language, pidgins emerged out of African, indigenous, and European imperfect syntheses, to become internally 'perfect' Creole languages. In medicine, the humoral system from Mediterranean classical antiquity fused with African curing programs and indigenous shamanism. The result was hundreds, perhaps thousands, of highly regional systems of health and curing that, in turn, served as vehicles of communication with people in other regions who had experienced similar cultural fusions. Religious syncretisms became the *modus operandi* of colonizing curates and of indigenous and African specialists in esoteric and numinous thought and reflection. Even horrors of the conquest were syncretized into indigenous and Afro-Latin American cultures (e.g., Hill, 1988; Whitten and Whitten, 2011).

For example, the battle cry of the Spanish conquistadors, '*Santiago!*' came from Santiago de Matamoros (Saint James the Moor Killer) as the Moors were defeated during the Castilian reconquista that was concluded in 1492, the same year that the Jews were expelled from Spain. It was used to mark Spanish territories in the Americas. After the reading of the 'Requirement' document informing all 'Indians' of their loss of rights to the Spanish, the conquerors yelled 'Santiago!' and attacked the natives with firearms, war horses, and war dogs, often feeding parts of the dead natives to the dogs, and rendering fat from the same dead natives to rub on the wounds of dogs and horses (Varner and Varner, 1983). Santiago underwent a ritual reversal in the Central Andes, where this saint became the patron icon of indigenous, Quechua-speaking peoples, and was called forth to resist the Spanish. Also in this region, and in parts of Amazonia, indigenous people say that some outsiders, whom they call *pishtaco* in Peru and *ñaqaq* in Colombia, seek 'Indian fat' for nefarious purposes. This may well be a modern reference to practices of the Spanish conquerors – an indigenous dimension of historical consciousness – although it is usually treated as an item of strange and curious native lore.

Cultural Continuities

In the face of radical transformations and syncretisms, continuities were also abundant. Amazonian languages such as Tupi, Arawak, Tukano, Tukuna, Jívaro, and Pano continued in their respective indigenous areas, with trade between different people also continuing, in spite of the efforts of the Catholic curates, first the Jesuits and Franciscans, and then others, to 'reduce' the populations to nucleated areas. Tupi itself, as Neenghatú, became the Lengua Geral of rural Brazil until replaced by Portuguese in the late nineteenth century, and the same language, as Guaraní, became the national language of Paraguay, where citizens spoke it along with Spanish. Quechua (including pre-Incaic) spread in the Andes to Argentina and in

Upper Amazonia, where it may have served as a language of trade. Today, at least 13 million people speak one of many dialects of Central and Peripheral Quechua, making it by far the greatest indigenous language family in the Americas. Many languages that defy classification with other known indigenous languages continue to be spoken today, especially in the Andean nation-states with substantial Amazonian regions and in the eastern countries of Brazil and the Guianas (see, e.g., Collier et al., 1985).

Rich realms of storytelling, often called mythology, are legion among native peoples, Afro-Latin American peoples, and people of 'mixed' descent, among whom they constitute sources of spirituality and historicity embedded in more than 100 languages (see, e.g., Hill 1988). They convey rich information ranging from medicinal plants to healing procedures to ways of thinking about humanity and society that confront the models of hierarchically organized and exploitative nation-state bureaucracies. Such telling of pasts motivates symbolically the development of political movements such as that of Pachakutik in Ecuador in the mid-1990s, and the Ecuadorian indigenous uprisings in that nation during the same decade, continuing into 2012 (Stern, 1987; Whitten and Whitten, 2011).

Within the socioeconomic classes oriented toward national politics, which have long been articulated to the global economy, the figure of the *caudillo* has loomed large since the end of the colonial era. A *caudillo* is a powerful figure, usually a man but sometimes a woman, such as the late Eva Perón in Argentina, who emerges in a time of political-economic or sociocultural crisis and attracts followers from many sectors of national life, including radically opposed political parties and classes. One of the greatest *caudillos* of all time was the liberator Simón Bolívar. The *caudillo* rallies such followers to his or her own personal benefit, thereby often losing considerable influence, and even office, when the crises are over. It is to the benefit of the *caudillo*, then, to maintain an aura of crisis, which in South America today, and back through its tumultuous history, is not difficult to do. The *caudillo* is matched in the indigenous sector by the *cacique* (sometimes called by the Quechua term *curaca*), who shares the qualities just described. (*Cacique* is also used for leaders in organized crime.) Both *caudillos* and *caciques*, as leaders in peripheral nations, depend in large part on economic gains to come from industrialized, wealthy nations. The cultural form of dependence of South American countries is closely tied to the developmental policies of the center nations, whose funding for externally designed projects often supports *caudillismo* and *caciquismo* (e.g., Whitten and Whitten, 2011).

Modernities and Alternative Modernities

Modernity among the elite and middle classes of South America is tied to urbanity, whiteness, and Euro-North Americanized consumer culture. The doctrine of *el mestizaje* serves these interests in the sense that the identity of mestizo underscores the processes of social whitening (*blanqueamiento*). Similarly, the representations as mestizo of those below the elite or middle classes refers to the darker complexions and stigmatized and racialized vulgarity of the common people, who in many nations constitute the vast majority. For people of indigenous and Afro-Latin American descent, and for others classed by the elite as 'mestizos,' modernity consists of passing back and forth among different systems of thought and behavior. In the past 15 years, the idea of interculturality, which refers to honing the powers of passage from one cultural system to another, has gained considerable momentum in many regions of South America (Whitten and Whitten, 2011).

Passages themselves give rise to new dimensions of power politics in South American nations, just as they gave rise to the Creole imagined nationalities of the nineteenth century (Anderson, 1991). The alternative modernities in the Euro-American-dominated global economy that spawned earlier state nationalism are now sowing the seeds of ethnic nationalism, manifest in many countries by the self-conscious rise of new nationalities out of the symbolic transformations and continuities of syncretic formations. Public displays of collective selfhood by indigenous people tap significant financial resources through nongovernmental organizations of Europe and North America, giving such social formations and movements a new articulation to economic resources. Black selfhood, however, does not attract significant financial resources.

The nations of South America vary greatly from one another, and the salient characteristics of their respective modernities also vary. Twentieth-century migration has changed the complexion of many countries, as Europeans (Jewish, Catholic, and Protestant), Middle Easterners (Jewish, Christian, and Islamic), and Asians (Chinese, Japanese, Korean, and Vietnamese) have become prominent actors in various class sectors. In the southern cone nations of Argentina, Chile, and Paraguay live significant populations of German immigrants. The ex-president of Peru, Alberto Fujimori, is the son of Japanese immigrants, and the Ecuadorian ex-president, Jamil Mahuad Witt, is the son of Lebanese and German immigrants.

South American nationality is often expressed through public performances as crystallizations of 'authentic' local-level or regional cultures (Guss, 1999). Concepts of cultural hybridity and alternative modernity fold ethnic and cultural diversity into a unified national pride. Festive centralization is often matched by local-level and regional divergence, as people in many walks of life appropriate nationalist stereotypes about authenticity into their own self-presentations. For example, indigenous people of Andean Ecuador have long performed individualized constructions of the European festival of Corpus Christi. Cultural images of rainforest inhabitants are evoked in these performances. In response to both the politicized indigenous movements and the craving of foreign tourists for 'authentic' Incaic performative reproductions, some of these festivals have been renamed 'Inti Raymi,' solstice of the sun. Performance of them becomes transformed into a nationalist, 'mestizo' rendition of Incaic authenticity and also an indigenous rendition of their increasing cultural spaces in the modern nation-state (Whitten and Whitten, 2011).

In the late twentieth century, nationalist governments used their expanding military powers to stress centralization and homogenization, and pan-Roman Catholicism continues to be a centripetal force at the beginning of the twenty-first century. Nonetheless, indigenous and black movements of South America, together with labor movements, feminist movements,

and various cultural emphases promoting counterhegemonic diversity, work against the exclusive imagery of ethnic blending in their respective nation-states and across national boundaries. New and dynamic cultural mosaics are constantly created out of the interplay of secular-sacred centralization, ethnic-cultural diversity, and interculturality. The dynamic, transformative balance between centralization and diversity that began in early colonial times continues into the beginning of the twenty-first century, although again, interculturality tempers this balance (Silverblatt, 2004).

New Socialisms, New Internationalisms, and Enduring Struggles for Diversity

ALBA, the Bolivarian Alliance for the Peoples of Our America, was conceived and constructed by President Hugo Chávez of Venezuela in 2004 to strengthen his socialist revolution in that country. It began as an international organization with an alliance with President Fidel Castro of Cuba, as an exchange of Venezuelan petroleum for Cuban medical assistance. Bolivian President Evo Morales joined the alliance in 2006 to strengthen his Movement to Socialism, and President Rafael Correa of Ecuador joined in 2009 to underscore the 21st Century Socialism movement. Other nations of the Caribbean and Central America also joined. In 2008, UNASUR, the Union of South American Nations, formed, and in 2009 its headquarters became lodged in Quito, Ecuador, and its parliament in Cochabamba, Bolivia. By 2010, UNASUR comprised all 12 South American nations. One explicit platform espoused from time to time by spokespeople in UNASUR is the goal to replace some of the functions of the Organization of American States (OAS), seen by many to be dominated by the United States, as the focus for South American development. Accordingly, plans are underway for a new currency, improved communications systems, and a regional central bank. UNASUR seems to represent a South American analog to the European Union. More recently, another organization, the Community of Latin American and Caribbean States has emerged to explicitly replace the OAS (Whitten and Whitten, 2011).

Within these alliances, the three South American nations of ALBA profess, in various degrees, an outright hostility to aid from and alliance with the United States and seek instead 'lateral' agreements with other countries, especially China, Iran, and Russia to the east, and Canada to the North. Iranian President Mahmoud Ahmadinejad has been especially active in courting alliances with Brazil, Venezuela, and Ecuador, and some US writers say his aim is to acquire uranium from South America in exchange for expertise in developing nuclear power there. The interest in nuclear power in Venezuela and Ecuador certainly exists, but it appears that the latter country, at least, has no uranium to mine, let alone exchange (Whitten and Whitten, 2011).

Paradoxically, to many, the ALBA nations, and to some extent those of UNASUR, have adopted plans, policies, and practices of neoliberal development, particularly in the areas of petroleum exploitation, gold mining, and copper mining, to promote and develop a system of redistribution to the poor and the ethnically disenfranchised (the latter often being indigenous and Afro-Latin American peoples). One of the most contentious and paradoxical issues that has arisen in these three countries is the privatization of water by large foreign and domestic corporations as a socialist strategy for development and to counter poverty. A key to the infrastructure of ALBA is the alliance of *caudillos*, with Hugo Chávez (before his death) and Evo Morales the most forceful, and Ecuador's Rafael Correa somewhere between leftist rhetoric and (at times) moderate practices and policies. The presidents of Brazil, Chile, and Argentina play moderating roles in their UNASUR positions that nonetheless influence the ALBA alliance.

In spite of their very strong public proindigenous and Afro-Latin American ideological positions, Chávez (who claimed descent from indigenous and Afro-Venezuelan parentage), Correa, and even Morales (himself indigenous Aymara) have taken very heavy-handed moves to disenfranchise indigenous people. This is done by giving state contracts to foreign countries to exploit subsurface resources in indigenous and Afro-Latin American territories. In all three countries, indigenous and Afro-American people (and those of other ethnicities) have been granted autonomous use of their land. But the state (in the three socialist countries, as in other nation-states of the region) holds all rights to subsurface resources to be exploited to help development. The regions most affected by subsurface exploitation run down the Andean zone on the eastern and western slopes and lowlands, where a large number of indigenous people and Afro-Latin American people reside. In the Andes, where the majority of indigenous people live, large-scale mining efforts overwhelm any efforts at native territorial autonomous usufructuary activities.

The result in the past decade has been a series of seemingly unending clashes between growing and allying indigenous organizations and the states of Venezuela, Colombia, Ecuador, Peru, and Bolivia. Blood has been shed on both sides of the state–ethnic divide, and possible solutions to the conflicts often lead to even more conflict and stronger international and intraethnic alliances. Added to these clashes are two factors: the socialist states seek stronger and stronger suppression of the free press, while indigenous and to a lesser extent Afro-Latin American peoples have increasing access to media outlets, especially through direct e-mail and websites easily found by Google and other search engines.

Finally, it must be noted that the participation of indigenous people, and to a lesser extent black people, in national literary, bureaucratic, developmental, governmental, and entrepreneurial activities has increased and is increasing. Urbanity, higher education, foreign travel, bilingualism or multilingualism, and other traits erroneously reserved for nonindigenous people are quite salient among indigenous people, and manifest by congressional representatives, physicians, lawyers, and scholars. In short, the nation-state images of indigeneity, as confined to rural regions and in need of state-sponsored development and especially training in Spanish and Portuguese, are erroneous. They take us back to the colonial imagery of the foundation of a Republic of Spaniards and a Republic of Indians, with no colonial space other than slavery for African descendants. It is against this imagery that the struggle for international recognition in their own right by indigenous and Afro-Latin American peoples sporadically surges and endures.

Abstract

This article outlines the major cultural periods that have been archaeologically documented in South Asia. Beginning with the Paleolithic and Mesolithic eras, the sequence of cultures from the Neolithic/Chalcolithic, Iron Age, Early Historic, and Medieval periods is presented, with some attempt to characterize the significant regional variation that is seen throughout time.

Nearly two and a half centuries of archaeological research in South Asia have uncovered rich and diverse traditions of prehistoric and early historic cultures spanning millennia. Data from excavation, survey, ethnoarchaeological work, and experimental research have provided a wealth of knowledge about the South Asian past that would be impossible to exhaustively detail in this short article. Although many have critiqued the practice of adopting a periodization scheme based on the European sequence or assumptions of social evolution, the chronology of South Asia is still conventionally divided into stages based on technology, typology, and subsistence regime – though absolute dating techniques also provide some anchors. This article will follow a roughly chronological sequence from prehistoric to modern times, and will outline major regional traditions associated with each period.

The Paleolithic

The Paleolithic is divided into Lower, Middle, and Upper phases, although other terms such as Pre-, Early, and Late Acheulean are also used. Stone tools associated with all three phases have been reported from across the Indian subcontinent. Many tools occur as surface finds but artifacts have also been recovered from stratified contexts. Many sites have extremely long sequences, though there is also discontinuity, indicating the transient and shifting nature of habitation during this time.

Early evidence for hominin activity across South Asia is sporadic until the early Middle Pleistocene, though there are claims that date back as early as 2.2 Ma at Riwat and the Pabbi Hills in the Siwalik deposits of northern Pakistan (Chauhan, 2009a). The earliest evidence consists largely of chopper and cleaver Oldowan or Mode 1 pebble tools that are found at several locations across the Indian subcontinent. The Lower Paleolithic is divided into core-flake and Acheulean industries. Early Acheulean assemblages dated prior to 400 kya are dominated by biface hand axes and choppers and distributed across the subcontinent, from northern Pakistan to Nepal, Karnataka, and in the Kortallayar valley in Tamil Nadu. Later Acheulean sites are more numerous, particularly in central and peninsular India, and are identified by a greater percentage of flake tools and use of prepared cores such as the Levallois technique (Ghosh, 1989).

The Late Acheulean–Middle Paleolithic transition is poorly understood as prepared core techniques persist into the terminal Pleistocene. Middle Paleolithic assemblages have been dated to between 125 kya and 40 kya, and are distinguished by a shift toward smaller tools and increasing use of siliceous raw materials such as chert, chalcedony, and jasper. Although only a few sites such as Nevasa in Maharashtra and Samnapur in the Narmada Basin are well stratified, Middle Paleolithic assemblages have been recovered from a wide range of ecological zones from the high-altitude environments of the Himalayan and sub-Himalayan regions at sites such as Sanghao cave near Peshawar in Pakistan, the Alakananda valley in Northern India, and Arjun 3 in Nepal, to the semiarid environment of the middle Krishna valley and Shorapur Doab in South India (Chauhan, 2009b).

The archaeology of the Paleolithic eras has mostly focused on the identification of stone tool types and understanding of subsistence. By the beginning of the Upper Paleolithic, evidence for more symbolic behavior is demonstrated by ornamental objects such as ostrich shell beads and circular stone platforms indicating possible ritual activity (Ghosh, 1989). Stone tool assemblages show a prevalence of parallel-sided blades and burins, and tools of other materials such as bone are also found. Important Upper Paleolithic sites include Baghor II in the Son Valley, Patne in Maharashtra, and Kurnool caves in Andhra Pradesh (Raju and Venkatasubbaiah, 2002). Hundreds of other Upper Paleolithic sites and finds have been documented across the Indian subcontinent, and show evidence for long-term but intermittent occupation. At the site of Bhimbetka, located in the Vindhyas, a series of occupations from the Lower Paleolithic onwards has been documented, and includes some of the earliest cave paintings in South Asia, dated to 30 000 BP (Chakrabarti, 1999).

The Mesolithic

The Pleistocene–Holocene transition is often associated with a 'Mesolithic' phase, which may be identified stratigraphically, or in terms of technology and subsistence. Like many transitional periods the South Asian Mesolithic is difficult to delineate and define (Chakrabarti, 1999). This phase is associated with the adoption of a wider spectrum of resources, and movement into a broader range of ecological zones than in

previous periods. Technologically, the Mesolithic period is characterized by small flake tools or 'microliths.' Although microliths are found during many preceding and succeeding phases of South Asian prehistory, their association with the Mesolithic remains strong, and the period is sometimes referred to as a 'microlithic phase' (Ghosh, 1989). Mesolithic remains have been reported across South Asia, often at sites with evidence for earlier Paleolithic occupation. However, only a few Mesolithic sites have been excavated including Bagor in Rajasthan; Chopani Mando in the Belan valley; and Sarai Nahar Rai, Mahadaha, and Damadama in the Ganga valley (Misra, 2002). In Sri Lanka, some of the earliest human remains have been discovered along with microlithic tools and artifacts made of bone and shell at sites such as Fa Hien Lena, Batadomba-lena, and Beli-lena, but sites dating prior to the Mesolithic are few and require additional verification (Deraniyagala, 1992).

The Neolithic and Chalcolithic Periods

As climatic conditions became more favorable during the Holocene, numerous communities across South Asia began the process of plant cultivation and animal domestication. This development is generally associated with the beginnings of the Neolithic period, but it is a process which began at different times across South Asia between the eighth and third millennia BCE. During this span of time, some regional cultures are characterized as 'Chalcolithic' based on the presence of copper artifacts. Copper begins to appear in limited quantities by the fifth millennium BCE, increasing in frequency over the next two millennia. Ground stone tools, early pottery, and evidence for permanent settlements are also associated with 'Neolithic' period sites across South Asia; however, there is much regional variability in Neolithic stone tool assemblages. Similarly, previous assumptions about the link between domestication, ceramics, and sedentism are now under question in many areas. Although there was a marked increase in sedentism between the eighth and third millennia BCE, various communities continued to practice more mobile lifestyles associated with pastoral or foraging subsistence strategies. This heterogeneity continues across South Asia to this day and must be factored into any consideration of past social dynamics.

Once believed to be a singular development, paleobotanical studies have now confirmed that agriculture was initiated at multiple locations across South Asia (Fuller, 2011). The earliest evidence comes from Baluchistan at the site of Mehrgarh in the Bolan valley, where the transition from seminomadic pastoralism to sedentary agriculture between the eighth and sixth millennia BCE may have been influenced by developments in Western Asia (Allchin and Allchin, 1982). Excavations at Mehrgarh yielded evidence for house structures, burials, and domesticates such as barley, wheat, and cotton. There is evidence for the gradual domestication of cattle, goats, and sheep, though wild game continues to form an important part of diet – this is a pattern seen across South Asia throughout time.

Several other sites in the northwest have provided evidence of small agricultural settlements between the sixth and fourth millennia BCE including Kili Gul Mohammad, Anjira, Mundigak, Gumla, and Sarai Khola (Ghosh, 1989; Singh, 2009). At these sites and many others, Neolithic levels are identified by features and artifacts such as mud brick structures, querns, pottery, and by paleobotanical and faunal evidence for domesticated species (Allchin and Allchin, 1982). Many sites and regions are associated with specific types of pottery traditions including Nal, Kulli, and Hakra ware sites. Copper objects, terracotta figurines, and beads made of semiprecious materials have also been recovered from Neolithic levels in many places, and excavated human burials attest to a variety of funerary customs during this time (Ghosh, 1989).

Elsewhere in South Asia, early Neolithic traditions have been documented in numerous regions, many having distinct traits marking them as potential loci of indigenous development. Rice is an early domesticate in the Ganga valley and surrounding plains, as well as in the northern fringes of the Vindhyas (Fuller, 2011). Though paleobotanical evidence for rice is documented from very early periods in these regions, understanding of its transition from a wild to cultivated crop remains ambiguous and is possibly dependent on the timing of hybridization of *indica* rice with *japonica* species introduced from China (Fuller, 2011). At sites such as Mahagara, Koldihwa, Chirand, and Senuar, Neolithic settlements have been dated from the fourth to third millennia BCE, though some earlier dates have also been suggested. In the Kashmir valley, Neolithic sites such as Burzahom and Gufkral are distinguished by the presence of plastered pit dwellings between the third and second millennia BCE. In the Northeast, Neolithic stone celts and axes have mainly been collected as surface finds. Neolithic levels at Sarutaru, Marakdola, Napchik, and Selbalriri have yielded some absolute dates in the range of the mid-second millennium BCE but there are suggestions that some of these sites may date to much later periods (Ghosh, 1989; Chakrabarti, 1999; Singh, 2009).

Further to the south, early agricultural village sites have been uncovered in Orissa and Bengal such as Kuchai, Gopalpur, and Pandu Rajar Dhibi, while in peninsular India, a number of Neolithic and Chalcolithic cultures have been documented, including the Ahar, Ganeshwar-Jodhpura, Malwa, and Jorwe complexes (Ghosh, 1989). These cultures have been dated from the third to late first millennia BCE and are contemporaneous with the Indus civilization. At sites such as Ahar, Gilund, Navdatoli, Daimabad, and Inamgaon, excavations have revealed evidence for copper artifacts in addition to stone implements. The presence of nonlocal materials such as shell, gold, ivory, and semiprecious stones indicates the existence of interregional networks of exchange across South Asia during this time.

In South India, the Neolithic traditions of the Southern Deccan are marked by unique patterns of material culture and paleobotanical evidence, suggesting this region was an independent center of early domestication. The cultivation of pulses and millets by the third millennium BCE at sites such as Hallur, Sanganakallu, Kurugodu, and Tekkalakota gradually intensified to include a wide range of local and introduced species (Fuller et al., 2004). A distinctive feature of the early 'Southern Neolithic,' confined mainly to Bellary and Raichur districts in Karnataka, are Neolithic ashmounds. These monumental accretions of vitrified dung indicate the importance of cattle in

the agro-pastoral economy and possibly represent the emergence of communal ritual activity (Paddayya, 1993; Johansen, 2004). Further south, Neolithic levels at Paiyampalli in Tamil Nadu have been radiocarbon dated to the mid-second millennium BCE. Very early dates have been suggested for the cultivation of barley, oats, and possibly rice in the Horton Plains (Premathilake, 2008), but overall the transition from the Mesolithic period to the better documented Iron Age remains poorly understood in Sri Lanka.

The Indus Civilization

As the small farming and pastoral communities of peninsular India began to develop, the earlier Neolithic societies of the Northwest were coalescing into a widespread tradition beginning in the fourth millennium BCE. The Indus or 'Indus Valley' civilization is also known as the 'Harappan' culture, in reference to the site of Harappa which, along with Mohenjo Daro, is one of the best known of the Indus urban sites. However, hundreds of other sites have now been documented across a vast region stretching from the foothills of the Himalayas to Iran and Afghanistan in the west, eastwards into the Ganga–Yamuna doab, and across Saurashtra to the Gulf of Khambhat (Kenoyer, 1998). These sites range in size from large urban centers greater than 100 ha to much smaller sites in the 1–5 ha range. Several periodization schemes have been developed to characterize the emergence and eventual decline of the Indus civilization including the Early (*c*.3200–2600 BCE), Mature (*c*.2600–1900 BCE), and Late (*c*.1900–1300 BCE) Harappan phases; a fourfold scheme of Early Food Producing (pre-6000–4000 BCE), Regionalization (4000–2500 BCE), Integration (2500–2000 BCE), and Localization (2100–1300 BCE) eras; and several more finely tuned regional and local chronologies based on pottery types or the stratigraphic sequence of a particular site (Ghosh, 1989; Possehl, 2002).

The earliest stages of the Indus civilization have been documented primarily along the Indus river system and in Kutch. This preurban phase is marked by the appearance of larger walled settlements and an overall intensification in agriculture, craft production, metallurgy, and trade. Many early sites such as Mohenjo Daro, Harappa, Rakhigarhi, Dholavira, and Ganweriwala grew into large cities by the mid-third millennium BCE (Kenoyer, 1998). In addition to this expansion, hundreds of new settlements were constructed across a vast and diverse landscape encompassing nearly one million square kilometers. Although much regional variation exists, this period is considered a time of standardization, stability, and general cultural efflorescence. With the exception of Saurashtra, where stone was frequently used, most Indus settlements were constructed of mud brick and baked brick architecture (Chakrabarti, 1999).

Hallmarks of the mature Indus tradition include the mass production of distinctive ceramic wares such as black on red Harappan ware and other large-scale manufacturing including shell working, bead making, and copper and bronze production. Thousands of seals and sealings have been recovered, many with common motifs such as the unicorn, humped bull, various wild animals, and a horned male figure sometimes referred to as a 'proto-Shiva' (see **Figure 1**). Many seals and other small objects bear short inscriptions in a logo-syllabic script that remains as yet undeciphered. Settlements of all sizes are laid out according to a walled grid plan, and have extensive water management systems for civic and domestic purposes (see **Figure 2**). Typical Indus craft items such as beads; shell ornaments; terracotta figurines; and objects of copper, bronze, silver, and gold have been recovered from many different types of sites, indicating the existence of strong intraregional networks linking villages, towns, and larger urban centers (Kenoyer, 1998; Possehl, 2002).

Figure 1 Harappan seal (from harappa.com).

Comparison of house sizes and human burials at many Indus sites suggests the existence of some social division and unequal access to wealth during this period. However, a distinctive absence of monumental architecture, opulent mortuary remains, or other forms of lavish elite display make it difficult to characterize the nature and structure of Indus society. Interpretations have ranged from ideas of centralized imperial control, to theories based on economic linkages (cf Ratnagar, 1991; Shaffer, 1982). Different interpretations of Indus religion have been put forward, including links to later Hindu practices. No Indus temples have ever been documented but evidence for ritual activity is materially marked by small objects and features such as figurines, ring stones, and brick-lined pits interpreted as 'fire altars.' Additionally, it has been suggested that the sophisticated hydraulic features found at most Indus sites indicate a ritual association with water or bathing (Possehl, 2002). Barring decipherment of the Indus script, or any more conclusive evidence, our understanding of religion during Indus times remains elusive.

Although our knowledge of political and social organization is still uncertain, the Indus civilization is typically classified as a 'state' level society, with features of complexity comparable to the contemporaneous Bronze Age societies of the Old World in Mesopotamia, Egypt, Western and Central Asia, and the Arabian Peninsula. Evidence for trade between

Figure 2 Mohenjo Daro (from harappa.com).

these societies has been documented by the sourcing of raw materials and artifacts, and by the Mesopotamian historical record. Harappan seals, pottery, and carnelian beads have been found at several sites in Mesopotamia, Western Asia, and the Persian Gulf, but few foreign artifacts have been recovered from Indus sites (Singh, 2009). Sumerian cuneiform texts referring to trade mention semiprecious stone; metals such as gold, silver, and copper; ivory; ebony; and various types of animals from 'Mehluhha' in exchange for fish, grain, and wool. Additionally, there is also evidence for exchange networks linking the Indus civilization to the Neolithic and Chalcolithic communities occupying other regions of South Asia (Possehl, 2002). The importance of trade and commerce to the Indus society is clear, and has been linked to both its

rise and fall. While trade may not have been a direct factor, it was certainly a significant activity in the Indus social and economic milieu and is an important avenue for further research.

The Iron Age

The second millennium BCE brought sweeping changes across much of South Asia, although the cause and nature of these transformations remain poorly understood. They have often been correlated with an overall contraction of Bronze Age societies in the Old World, but explanations of this broader decline remain speculative and the phenomenon is most likely due to a number of environmental and social factors. In the Northwest, the 'Localization' era of the late Indus civilization is characterized as a time of dissolving urban traditions and diminishing long-distance and interregional interaction. Settlements decrease in terms of both size and number, and there is a significant shift in material culture that varies by region.

Distinctive cultures such as the Jhukar and Cemetery H groups are identified by new forms of pottery and inhumation in the posturban layers of sites in Sindh and Punjab. To the north, the Gandharan Grave Culture has been dated from the early second millennium to the third century BCE and is characterized by a number of inhumation styles, objects of copper and bronze, and some evidence for iron and horses (Singh, 2009). The material cultures of these regions show some continuity with pre-Harappan and Harappan traditions but also have links with Central Asia. Theories that northern 'Aryan' invaders were responsible for the Indus decline have now been widely disproven but there is evidence for a gradual migration of Indo-European speaking groups into the Indian subcontinent during this period. These groups are difficult to trace archaeologically but linguistic studies have linked them to the origins of the Sanskrit language and the earliest layers of Vedic tradition. It is likely that the practices of these new groups merged with the indigenous traditions they encountered to form the ritual and social customs that developed in the post-Indus period. Although agriculture practices continued to diversify during this time, a shift toward pastoralism is often hypothesized.

The post-Indus period is conventionally depicted as illiterate and nonurban but there is strong evidence to suggest continued settlement in many regions, particularly to the east and south of the Indus valley. Sites such as Daimabad in the upper Godavari Valley and Rojdi in central Saurashtra show some evidence for expansion during later Harappan levels (Possehl, 2002). Archaeologically, the cultures of northern and central India are identified through a range of material forms such as Ochre Coloured Pottery, which has been discovered at sites across the Ganga–Yamuna doab, and copper hoards found primarily in the upper Ganga valley and eastern India (Ghosh, 1989). In addition to copper objects, more widespread evidence for iron use is documented across South Asia between the mid-second and mid-first millennia BCE and thus the period is increasingly referred to as the 'Iron Age,' though the use of 'Vedic period' as well as regional terms also persists. Iron yielding levels are associated with a ceramic type known as 'Painted Grey Ware' from the Indus to Ganga valleys.

In peninsular India, continuity is seen at many earlier Neolithic and Chalcolithic sites, where the Iron Age is associated with an intensification in agricultural practices, increasing settlement size, and the construction of monumental features known as megaliths. Megaliths have been documented in various contexts across South Asia and in many regions may have been built up until recent times (Moorti, 1994). Megaliths dated to the Iron Age are constructed in a range of forms such as dolmens, cairns, menhirs, and circular alignments. Some contain human inhumations and various objects such as iron implements, pottery, or faunal remains (Moorti, 1994; Brubaker, 2000–2001). In addition to mortuary purposes, megaliths were sometimes constructed to mark socially differentiated space and thus may serve as an indication of increasing political complexity in South India (Bauer, 2011). A ceramic type known as 'black and red ware' begins to appear more frequently, though it is seen during earlier and later periods as well. The Iron Age in Sri Lanka is also better documented than previous periods. At sites such as Anuradhapura and Ibbankatuva, early iron bearing levels have been dated as early as the eight and ninth centuries BCE (Deraniyagala, 1992).

The Early Historic Period

As with other cultural periods in South Asia, the Early Historic has varying start dates across different regions. By the sixth century BCE, many settlements begin to grow into cities once again, thus marking the beginning of what is known as the 'second urbanization' in northern India (Allchin, 1995). Initially centered in the Ganga valley, this urban expansion continued to spread across the northern and northwestern Indian subcontinent over the next two centuries and is associated with early literary traditions and the emergence of small regional states known as *janapadas*. Though there are no extant written records, several later texts have been assigned original composition dates of the mid-first millennium BCE. The political genealogies suggested by these texts can be cross-referenced with the numismatic record which also emerges around this time. Additionally, the development and spread of heterodox religions such as Buddhism and Jainism contribute their own traditions of literary and material culture.

In South India, the Early Historic period begins about three centuries later, and is based on the date of the Asokan edicts which are written in the Brahmi script, and also in Kharosthi. These inscriptions, which are distributed across the Indian subcontinent, are associated with the third king of the Mauryan Empire (*c*.320–180 BCE), and are the first extant inscriptions to be found in South Asia (see **Figure 3**). Though several possible origins for the Brahmi script have been proposed, its earliest development is still unclear. Research from Tamil Nadu and Sri Lanka has recovered graffiti-marked sherds from layers that

Figure 4 View of Sisupalgarh eastern rampart (courtesy of Monica Smith).

predate the Mauryan Empire (Deraniyagala, 1992; Mahadevan, 2003). These early dates may substantially revise our understanding of Brahmi, which is often attributed to foreign or north Indian origins.

With the advent of written records, the narrative of the South Asian past becomes less reliant on archaeology and the study of material remains. Nevertheless, historic period archaeology in South Asia has a long record of research, dating back to the historical geography of Colin Mackenzie in the late eighteenth century. Early archaeological research focused largely on monumental remains such as the early Buddhist stupas at Bharhut, Sanchi, and Sarnath. However, excavations in the early twentieth century at Pataliputra and Bhita in the Ganga Valley, and Taxila in the northwest gave some indication of the growth and character of the renewed urbanism that emerged during the Early Historic period (Chakrabarti, 1995). Although hundreds of cities and smaller settlements have been identified across South Asia, excavations have been limited as occupation at many sites has continued up until the present day. This significantly complicates efforts at more intensive exploration. Settlement evidence from survey and excavation research is often contrasted with details from Puranic and early Buddhist texts and with external references in Greek and Roman literature. More recently, remote-sensing techniques have been employed at sites such as Sisupalgarh and Kausambi in order to clarify additional details about city layout.

Layers associated with the Early Historic period are identified by diagnostic artifacts such as Northern Black Polished Ware, punch-marked coins of bronze and silver, beads made of semiprecious stones such as carnelian and lapis lazuli, and terracotta figurines (Ghosh, 1989). Many cities including Kausambi, Rajgir, Ahicchatra, Mathura, Atranjikhera, Chandraketugarh, and Sisupalgarh are surrounded by extensive ramparts and fortification walls which may have served both defensive and symbolic purposes (Allchin, 1995) (see **Figure 4**). Craft production areas have been identified at sites such as Ujjain (Ghosh, 1989), and more recently at Indor Khera (Menon and Varma, 2010), but understanding of settlement organization remains incomplete. Knowledge of Early Historic social life is still largely reliant on interpretations from the historical and epigraphic records. Inscriptions in Brahmi, Karoshti, and later regional scripts are found with increasing frequency from the third century BCE onwards and are carved in stone and later on copper plates and other objects. As both text and material artifact, the epigraphic record provides a wealth of detail on political, economic, and social forms during the Early Historic and later periods in South Asia.

In peninsular India, most settlements remained relatively small during the first part of the Early Historic period, though some sites such as Anuradhapura in Sri Lanka may have reached urban proportions quite early (Coningham, 1999). While the *janapadas* of the north and northwest were being absorbed into imperial polities such as the Mauryan Empire, the late Iron Age communities of southern India were steadily growing into larger settlements supported by diversifying subsistence regimes that included new cultigens such as rice. New styles of pottery such as Rouletted Ware and Russet-Coated Painted Ware are associated with Early Historic deposits (Allchin, 1995). Although conventional narratives claim that much of south India was incorporated into an almost pan-Indian Mauryan Empire by the third century BCE, recent research has proposed that interaction with northern imperial forces may have been much more limited (Ray, 2008; Sugandhi, 2013). Nevertheless, there is some evidence to suggest the deliberate articulation of northern forms of sovereignty and local traditions of authority during the Iron Age/Early Historic transition in the south. This begins the gradual incorporation of South India into the wider 'pan-Indic' customs characteristic of the latter half of the Early Historic period. This is first seen through the construction of Buddhist monuments, and later by the adoption of Brahmanical political and ritual traditions. Buddhist sites with initial dates of construction as early as the second century BCE have been documented at Kanaganahalli in Karnataka and Amaravati in Andhra Pradesh. Sri Lanka also has many early Buddhist structures that date to Early Historic times. According to historical sources, the first stupa at Anuradhapura was built in the mid-third century BCE (Coningham, 1999).

In contrast to earlier models of imperial conquest, recent narratives look to politically independent networks of commerce and religion as mechanisms of exchange and

integration between the cultures of the north and south (Ray, 2003). Evidence for large-scale craft production has been documented at sites such as Kodumanal in Tamil Nadu and Mantai in Sri Lanka, indicating participation in early economic networks. Trade items from the Mediterranean region have been identified at sites such as Arikamedu in Puducherry, Pattanam in Kerala, and at sites in Sri Lanka. Collectively, this evidence, along with written records, testifies to the early incorporation of South India and Sri Lanka in the interregional and long-distance relationships that traversed South Asia and connected it to the wider world (Ray, 2003). These connections certainly warrant further research in order to better understand the processes of integration that developed across the Indian subcontinent during the Early Historic period.

Understanding of religious networks has largely been inferred from the literary and epigraphic records but can also be understood from the distribution of monastery sites, which are often located at important points along trade routes. Early Historic ritual architecture is largely confined to Buddhist stone structures and the rock-cut caves of the Western and Eastern Ghats, which are mostly Buddhist and Jain during the earliest phases of construction. However, by the close of the Early Historic period, these traditions were on the decline, as the newly emerging *bhakti* (devotional) traditions of Hinduism began to take hold across the subcontinent. The earliest surviving Hindu temples are built of stone and have been dated to the first few centuries of the Common Era (Singh, 2009). Early temples were small structures that are sometimes difficult to identify, but over time they grew into larger complexes such as the sixth-century CE Vishnu temple at Deogarh in Bihar and the seventh-century CE Durga temple built at Aihole in Karnataka (Sugandhi and Morrison, 2011). They are most likely predated by wooden or brick structures, which often form the early core of later stone constructions.

From the limited archaeological evidence available, it is clear that the Early Historic period was an extremely dynamic time in South Asia which saw the emergence of a number of significant and enduring traditions, many of which continue up until the present day. Efforts to encapsulate these multiple developments within a single cultural period have proven frustrating for archaeologists attempting to characterize the regional variation observed in the material record. Nevertheless, understanding this variation remains an important goal in historic period archaeology of South Asia, and efforts to revise the chronology in order to reflect this are currently underway.

The Medieval and Modern Periods

Archaeological research on the subsequent Medieval and Modern periods (*c.*500–1500 CE, 1500 CE–present) is quite limited in contrast to the fields of art and architectural history. Studies of material culture have mostly focused on monumental architecture such as temples and forts, and on the numismatic and epigraphic records. Although many historic settlements across South Asia continued to be occupied into medieval times, little consideration has been given to these remains. An important exception is the research that has been conducted in the Tunghabhadra corridor in Karnataka around the city of Vijayanagara, capital of an imperial polity that held sway over much of South India between the fourteenth and sixteenth centuries CE (see **Figure 5**). Archaeological studies at Vijayanagara have examined issues of craft production, investigated the distribution of sites across the wider metropolitan area, and examined the effects of long-term human land use through paleobotanical studies (Sinopoli, 2003; Sinopoli and Morrison, 2006, 2009). With the start of the Modern period (*c.*1500 CE), the line between archaeology and the history of the discipline becomes blurred. Though a few projects have looked at the colonial use of space, archaeological studies of the Modern period are scarce.

Figure 5 Entrance to Vitthala temple, Vijayanagara (personal photograph).

Discussion

In closing this article of South Asian archaeology, a few final points should be noted. As the descriptions above have hopefully made clear, there is a tremendous amount of variation within and between the different cultural traditions that have been identified by archaeologists over time. As research continues to document this diversity, it is increasingly evident that the immense complexity of the South Asian past is only partially represented by existing culture historical classifications. Moreover, advanced techniques of analysis such as thermoluminescence and isotope studies continue to revise our understanding of chronology, social process, and transition across both space and time.

Although the continuous nature of occupation at many historic and prehistoric sites may provide valuable data on long-term human–environment interaction, it also raises the challenge of site destruction. Much archaeological research conducted in South Asia may be classified as 'rescue work' as modern processes of agriculture, construction, and mining threaten thousands of sites. Attempts at mitigating this destruction include community outreach programs and heritage management strategies adapted to fit the South Asian context. The development of increasingly efficient documentation methods also holds much value, as the pace of contemporary development rapidly outstrips preservation efforts.

Finally, the political use of archaeological knowledge must be mentioned and cautioned against. From the destruction of the sixth century BCE Bamiyan Buddhas in central Afghanistan to the court-ordered excavation of the Ram Janmabhoomi site at Ayodhya in northern India, recent events in South Asia have highlighted the significance that can be attached to archaeological remains and the way perceptions of the past may be used for contemporary political purposes. Archaeology is a science grounded in fact, but it is also an interpretive discipline conditioned by the biases of researchers and the public alike. Future studies must strike a balance between objective research goals and reflection on these more subjective factors as it continues to document various aspects of the South Asian past.

South Asian Legal Traditions

Rohit De, Department of History, Yale University, New Haven, CT, USA

Published by Elsevier Ltd.

Abstract

South Asia (comprising the present states of India, Pakistan, Afghanistan, Nepal, Bhutan, Bangladesh, Sri Lanka, and the Maldives) is marked by the diversity of its legal traditions. The founders of comparative law, when dividing the globe into different legal systems, describe South Asian legal culture as Hindu law. However, South Asia is the site for Hindu, Muslim, Buddhist, tribal, British colonial and postcolonial legal regimes, along with the presence of Jain, Zoroastrian, French, Portuguese, and Roman-Dutch legal systems. Unique to South Asia is the fact that while these legal traditions appeared at different points of time, none was able to supplant the others completely and had to evolve a relationship of coexistence.

South Asia (comprising the present states of India, Pakistan, Afghanistan, Nepal, Bhutan, Bangladesh, Sri Lanka, and the Maldives) is marked by the diversity of its legal traditions. The founders of comparative law, when dividing the globe into different legal systems, describe South Asian legal culture as Hindu law. However, South Asia is the site for Hindu, Muslim, Buddhist, tribal, British colonial and postcolonial legal regimes, along with the presence of Jain, Zoroastrian, French, Portuguese, and Roman-Dutch legal systems. Unique to South Asia is the fact that while these legal traditions appeared at different points of time, none was able to supplant the others completely and had to evolve a relationship of coexistence.

Given the constraints of space, this article will focus primarily on the mainland subcontinent (India, Pakistan, and Bangladesh) with a few references to other traditions.

Ancient Indian Legal Traditions

The period from 600 BCE until about the twelfth century AD has been described as the heyday of Hindu law, evidenced by the proliferation of Sanskrit legal texts and commentaries. However, Hindu law stands as markedly different from other religious legal traditions. There is no definite starting point or any doctrinally central event and no central text or figure of a lawgiver (Menski, 2003a). Hindu law is better understood as a family of laws rather than a single unit, functioning at several different registers (Menski, 2003b). Orientalist scholars searching for a code of Hindu law would turn to the large corpus of Sanskrit texts (numbering in the hundreds) that are collectively known as the *Dharmasastra* (Kane, 1968). The Sanskrit word *dharma* has often been translated as law, though in reality it's a more complex concept evolving from the root *dhrt*, which means to 'hold, maintain, and keep.' Dharma signified appropriate behavior and encompassed duties, rights, moralities, conduct, virtues, and obligation. The Dharmasastra texts addressed three major topics: *achara* or appropriate behavior and rituals for different castes and different stages in one's life; *vyavahara*, the rules for resolving doubts about duties; and finally *prayaschitta* or rules about penances for violating dharma. While the earlier dharmasastras assumed compliance, the later texts emphasized punishment or deterrence to ensure that obligations are fulfilled. Rights, obligations, and punishments were all determined by caste, age, and status. Arguably the most famous of the *Dharmasastra* is the *Manusmriti*, or the Code of Manu, which was translated by the orientalist Sir William Jones in 1794. The *Manusmriti*, which laid down elaborate rules governing the behavior of castes and social groups, was celebrated as a compendium of laws because it was one of the first texts that drew authority from dharma itself rather than the gods. However, the primacy given to the Manusmriti has more to do with the limits of colonial imagination that was seeking a law code, rather than its actual reach and influence. Written at the time when organized Hinduism was being challenged by Buddhism and Jainism, the Manusmriti was seeking to shore up the authority of the caste system.

Despite the sophistication of the Dharmasastras or the prestige of their authors, it is unclear how much influence they had on governing everyday lives. These texts propose ideal models of social reality and there is limited evidence on the lived experiences of law. Historical accounts suggest that in most cases, local communities, caste groups, and villages retained considerable autonomy to decide disputes on custom or conventions that they could themselves evolve. Appeals from these did go to royal authority, but most state courts also decided the dispute relying on the community's practices.

Unlike its contemporary civilizations, there is nothing to suggest that there existed any class of persons versed in the Smriti whose profession was similar to that of modern lawyers (Kane, vol.3, 1946, 288). There are only isolated references to the term *niyoga* (or appointed in lieu of), which is the closest one can get to a professional class of lawyers; however, the main requisite here was a personal connection to the petitioner and not legal competence. Some classical scholars have argued that the class of lawyers was not required in Hindu law, because the administration of justice was the concern of the King, who had to ensure not only that the guilty were punished but also that the innocent were not prosecuted (Rocher, 1968).

Islamic Polities

While Muslims have been present in the subcontinent since the eighth century, it was in the eleventh century that the first Islamicate polities were established in the subcontinent following conquests in North India by Persianized Turks. During a period of turmoil in Central Asia, these rulers drew

legitimacy from the fact that they provided order and allowed Islamic life to flourish. Most courts patronized Sufi shaykhs and royal authority was closely tied to their shrines. A number of Muslim dynasties established control over large parts of north, west, and central India, the largest and most influential being the Mughal empire, which during its heyday (1526–1707) extended over most parts of contemporary South Asia.

Notionally, much of the subcontinent was governed by sharia law. However, in practice the sharia was not a rigid legal sacral system in South Asia. While Mughal commentaries on sharia law, such as the Fatwa-e-Alamgiri, explicitly state that the sharia was not applicable to non-Muslims in the subcontinent, historical evidence suggests that it came to be appropriated by all sections of society and formed the basis of a shared normative system. As Farhat Hasan shows, Hindu merchants frequently invoked provisions of Islamic law on the sale of property when dealing not just with Muslims but also with other Hindus. More strikingly, Hindu and Muslim women frequently appealed to sharia principles and moved state authorities to secure their claims to property and guardianship (Hasan, 2004). The sharia through the Mughal period was tied to local power relations, and became the arena of conflict of different social groups. Similar to findings in studies of Ottoman territories, women seem to have possessed a high degree of legal consciousness and were frequent actors in the courts. As Hasan has argued, several marginal groups resisted the powerful through "an insurrectionary awareness and acquisition of the dominant legal discursive system" (Hasan, 2004, p. 75).

It is important to note that even under Mughal rule, which saw a higher degree of centralization than earlier states, the state legal system barely permeated rural areas. The courts, the *qazi* (Islamic judge), the *faujdar*, (constable), and other legal institutions were primarily urban. Disputes and law enforcement in rural areas continue over the centuries to be dealt with by bodies called *panchayats* or local assemblies of notables. These could exercise jurisdiction over a territory like a village, a caste group, or a kin group.

While most litigants appearing before the courts represented themselves, by the seventeenth century there is the emergence of a class of men called *vakils*, who resembled modern lawyers. However, a vakil was usually invested with the authority to act for another but not necessarily plead for him before a court of law. European travelers commented both on the absence of lawyers from courtrooms and on the relative simplicity and efficacy of state courts. Under Emperor Aurangzeb's reign, the state began appointing vakils to look after various interests including to act as legal advisors to the poor (Calkins, 1969).

The Company Period (1601–1833)

In 1601, Queen Elizabeth I granted a charter to the English East India Company (EEIC) giving them the monopoly over trade with India. The EEIC successfully negotiated permission from Indian rulers to set up factories and port towns in Surat, Bombay, Calcutta, and Madras. The royal charters empowered the EEIC officials to administer justice in their territories. The charters required that all Company laws had to be 'reasonable' and not contrary to the laws and customs of the English realm. The charters had only granted the Company the jurisdiction over English subjects, but it soon found itself dealing with Indians who pursued claims in the Company courts as well. The Charter of 1726 established an 'Anglo-centric' legal order in Madras, Bombay, and Calcutta, which brought the Indian territories firmly into the British legal world. It explicitly provided that the law of the Company settlements in India was to be that of England, to the extent that circumstances would permit. It set up Mayor's courts headed by aldermen who were tenured for life, guaranteeing a degree of independence, and explicitly provided for appeals to the Privy Council. As recent scholarship has shown, judges and juries in these Company towns frequently protested deviations from English law and the arbitrary authority of the Company officials (Fraas, 2014).

However, both the nature of colonial rule and the legal system were transformed following the victories of the EEIC in the battles of Plassey and Buxar. From being an armed trading power, the Company found itself sovereign over territory greater than the size of Germany. Over the next 50 years, the Company state made three interventions that transformed South Asian legal cultures completely.

The colonial state, with its investment in creating a rule of law, displaced local authorities through new civil courts and formal procedures. Litigation became central to the creation of the colonial state. British legal procedure was based on the normative idea of equality, understood relationships in contractual terms, sought to arrive at a specific decision and saw a dispute as a discrete problem (Cohn, 1987). Indian society was not premised on equality or contract between individuals, but sought to locate them within a network of social relationships. Indigenous forms of dispute resolution instead postponed clear-cut decisions and aimed at compromise. Cohn argued that this made courts the site of a direct clash of the values between British and Indian society. Indians used the courts as a form of speculation or gambling. Given the cost and time involved, litigation was often a threat, rather than a method of resolving disputes. With the demilitarization of society, litigation became the new battleground and a form of public entertainment (Cohn, 1987, p. 573). This view was shared by colonial administrators who sought to police the 'lying, litigious native' by increasing court fees, punishing perjury, and changing evidentiary practices (Raman, 2012).

Secondly, despite the promise of the rule of law, it was marked by its absence in many aspects of colonial government. Scholars have argued that the rule of law was bound to fail in a colonial context, since colonial difference marked by race determined the relationship between the state and the individual. Legislation that sought to allow Indian judges to try Europeans was faced with widespread protests and had to be withdrawn. Executive authority was shielded from judicial oversight and the powers of the appellate courts were trimmed over successive years. Attempts to rationalize the administration and make it less arbitrary would constantly run up against the question of race and the relationship between the colonizer and the colonized. Indeed, the logic of the colonial state can be demonstrated by the way in which the provision for exercise of arbitrary power was incorporated into legal codes and normalized (Kolsky, 2005).

Finally, the colonial state created the domain of personal law. In an attempt to maintain the veneer of legitimacy granted by the Mughal state, the British administration had continued

to apply the law of Hindus and Muslims to matters of inheritance, marriage, and religious institutions (Kugle, 2001). Under the 1772 Regulations, Governor-General Warren Hastings stated that "inheritance and succession to lands, rents, and goods, and all matters of contract and dealing between parties, shall be determined in the case of Mahomedans by the laws of the Mahomedans, and in the case of Gentoos (Hindus) the laws and usages of the Gentoos" (Kugle, 2001). Hastings believed he was continuing the practice of the Mughals, who had left each non-Muslim community the right to administer its own law to its own members as long as they met certain conditions. However, the analogy was false since the Company state itself administered the law of each religious group. This magnanimity toward preserving indigenous law was selective. Initially, English judges were assisted by Hindu pundits and Muslim qazis in administering personal laws. However, the distrust of native judges led to their gradual removal from courts and the dependence of English judges on translations and volumes of precedence. The conversion of a relatively fluid localized system of Islamic law to a reified and static entity through "translations, codification, and adjudication" has been documented extensively by scholars (Anderson, 1993; Kugle, 2001). The British saw the sharia as analogous to canon law in Europe and attempted to discover an authentic code in an authoritative text. Thus, British courts narrowed down the number of precepts accepted as Muslim law while simultaneously giving finality to sharia, which it could not attain when authority was localized and distributed amongst the many jurisdictions and individuals. Similar interventions by the colonial government created a body of law often described as Anglo-Hindu law.

Buddhist and Jain legal traditions remain less well known in mainland South Asia, partly because of their underrepresentation in the colonial legal system. Scholars speculate that the British believed that the Jainas had no legal texts because the Jainas deliberated concealed their scriptures from British law to prevent the texts from being defiled. With the annexation of Burma a corpus of Buddhist legal texts were translated from palm leave manuscripts, but these largely dealt with rules for Buddhist monastic order and not for laypeople. What came to be defined as Buddhist law in Burma, consisted largely of customary practices of Burmese people who happened to be Buddhist. The Zoroastrian community or Parsis, became spectacularly successful legal entrepreneurs in harnessing the colonial legislature and judiciary to develop a Parsi law in the late nineteenth and early twentieth century. Recent scholarship suggests that Parsis enjoyed greater legal consciousness and were overrepresented both as litigants and as judges and lawyers within the colonial legal system (Sharafi, 2014).

Similar processes were observed when the colonial state sought to apply customary law, particularly areas inhabited by the thousands of tribal communities. However, by the process of recording, translating, and adjudicating custom for the colonial law courts, the nature of customary practices was transformed. Tribal groups remained ambivalent about the colonial readings of their customs, and on several occasions, asserted their customary rights over land and forests through demonstrations or open rebellion (Bhattacharya, 1996). In Afghanistan and the North Western province of Pakistan, informal institutions such as *shuras* (local councils of elders or religious scholars) and *jirgas* (councils of elders of the Pashtun tribes) continued to coexist alongside both colonial and postcolonial legal systems. In resolving disputes, they drew upon developed conceptions of morality and justice such as the Pashtunwali (the Pathan Code of honor). While overwhelmingly Muslim, these bodies frequently deviated from sharia practices on questions like inheritance rights for women.

These developments were mirrored in Sri Lanka, which had first come under European control by the Portuguese and then by the Dutch. On gaining control of the coasts, the Dutch introduced Roman-Dutch law. Dutch courts, like English ones in India, also administered customary and religious laws of the local Sinhalese and Tamils. The Dutch officials sought to codify these bodies of law and produced the *Thesawalamai*, or a treatise on the laws and customs of the Tamils of North Sri Lanka, in 1794. With the British conquest of Sri Lanka, the existing framework of laws was continued and Roman-Dutch law coexisted with English common law and customary law. The British conquered Kandy, the last autonomous state in Sri Lanka, and applied Kandyian law to the people from the region (Cooray, 1974). Like the Indian system of personal laws, the Sri Lankan laws were also applicable to people based on their origins. So a person who is originally from Kandy will continue to be governed by Kandyian law even if she resided elsewhere.

As the above processes demonstrate, the colonial state had transformed localized legal systems into overarching, textual bodies of law through a process of translation, codification, and adjudication. However, forum shopping continued to be a way through which litigants continued to maneuver the system. Groups resisted categorization into religious communities by claiming customary practices that differed; for instance, the Khoja Muslims of Bombay were successfully able to claim that they were governed by Hindu family law. In the absence of divorce provisions, women would convert to other religions in order to dissolve their marriages. Businesses and individuals would take advantage of the semiautonomous princely states that were not directly governed by the British to escape onerous legislation (Sharafi, 2010; De, 2010).

Portuguese-controlled territories were an exception to this religious patchwork and governed all subjects through the Portuguese Civil Code of 1867. In independent India, former Portuguese territories like Goa continue to have a uniform civil code in force. In these maneuvers the litigants were helped by the rapid growth of the modern legal profession in India. Indians had staffed the lower level legal positions from the earliest days of the Company rules; by the end of the nineteenth century they came to dominate the bar and rise to the bench. The explosion in the number of lawyers led to complaints about brieflessness and unemployment. As figures familiar with the colonial state, and one of the few groups not dependent on the state for their income, lawyers also began to dominate the Indian national movement. India today with over 1.2 million lawyers has one of the largest pools of legal professionals after the United States and in contrast to other peers like China and South Africa. However, on a per capita or per GDP basis, India ranks a lot lower. The legal profession in India, as in its neighboring countries, remains highly segregated with a small tier of highly paid lawyers and a large mass of struggling low-income professionals (Ganz, 2011).

High Colonial State and the Codification Projects

While religious laws continued to govern areas like marriage and inheritance, Islamic civil, criminal, and commercial laws were rapidly replaced by British legislation, given that law and order and commerce were both critical aims of the state. However, it was in the mid nineteenth century that utilitarian-minded bureaucrats were able to start a mammoth project of codifying civil and criminal law. Successive law commissions headed by Lord Macaulay, James Fitzjames Stephens ,and Henry Maine, enacted the Indian Penal Code, the Codes of Civil and Criminal Procedure, and the Evidence Act. The codification of procedural laws could encompass the utilitarian desires of unity, precision, and simplicity without intervening with the substantive content of the law (Metcalf, 1997). As utilitarian attempts to codify the law in the United Kingdom had been fiercely resisted in parliament, therefore South Asia came to serve as a laboratory. These codes that were originally written for India were exported to other British colonies in Asia and Africa. Entrepreneurial Indian lawyers who had gained experience with these legislations would set up practice in colonies like Fiji, Malaysia, or Kenya. Many of these colonies also had growing populations of South Asian immigrants, either in the form of merchants or as coolie labor. M.K Gandhi was one of the most prominent of these diasporic lawyers. Thus, South Asian legal culture, including the system of personal laws, was also exported through imperial networks.

Autonomous states like Nepal and the semiautonomous princely kingdoms in India often pioneered new legal reforms. The state of Baroda introduced a divorce law for Hindus in the late nineteenth century, Bhopal granted more rights to Muslim women and the state of Mysore was the first in the world to introduce affirmative action for lower castes in employment, education, and legislatures. Processes of centralization were more prevalent in these 'semiautonomous' territories, for instance the Nepali state through the nineteenth century broadened its powers to intervene in questions related to caste and jati rules, a matter that in British-controlled territories were left to caste groups themselves.

Postcolonial Legal Orders

India and Pakistan became independent in 1947, Sri Lanka in 1948. At various dates, each state adopted a republican constitution, including a judicially enforceable bill rights. Unlike the colonial state, the new states explicitly granted courts the power of judicial review and the ability to strike down legislation and administrative orders as unconstitutional. Unsurprisingly, in both democratic India and increasingly authoritarian Pakistan, tensions arose between the judiciary and the executive over the ability of the state to amend fundamental rights or the legality of marital rule (Austin, 2003; Newburg, 2004). While creating a powerful set of constitutional remedies, the new constitutional orders retained several techniques of colonial governance. For instance, the colonial institutions of the police, the army, and the bureaucracy remained structurally largely unchanged. The constitution recognized provisions where the executive could declare emergency and suspend fundamental rights. Even the fundamental rights that were granted were subject to certain textually inscribed limitations, for instance, freedom of speech was subject to limitations on grounds like public order, decency and morality, incitement to offense, sovereignty and integrity of the state, etc. Unlike the U.S. constitution which sought to protect its citizens from the government, South Asian (particularly the Indian) constitutions sought to empower the state. This is partly because the authors of the constitution envisioned it as a document that would bring about social transformation and economic redistribution.

Finally, the constitutions for the first time in South Asian history declared all citizens to be equal before law. The most drastic change from the precolonial system was the displacement of a normative inequality as the ground for conceptions of rights in India. Rights under colonial government were determined by caste, class, and gender and drew upon 'custom' (Guha, 2000). The Constitution however heralded a formal equality between all citizens, and created a common source of rights for all. The Indian constitution specifically abolished untouchability, and also provided for a wide range of affirmative action programs for certain castes and tribes, as well as women. The states of Pakistan and Bangladesh would also come to recognize the principle of substantive equality and provide for affirmative action for women in legislatures.

All South Asian states have tried to reconcile the existence of personal laws (which are often highly discriminatory) with constitutional equality. It has been suggested that the codification and control over the interpretation of the sharia mirrored the process of vesting political power away from Muslims. Not surprisingly, a significant component in the growth of Muslim nationalism was the attempt to regain control over this system. The early legislatures had attempted to reform family law in the 1930s, often to address questions of gender justice. In 1939, the Dissolution of Muslim Marriages Act provided Muslim women limited grounds for divorce (De, 2009). After independence, the Indian government in face of much opposition from Hindu conservatives was able to push through the Hindu Code bill, which replaced Hindu family law with statutory law. While codifying elements of Hindu law, the code provided for divorce and gave certain inheritance rights to women. Similarly, in Pakistan, the Family Law Ordinance of 1961 attempted to temper sharia law by making it institutionally difficult to practice polygamy, restricting the man's unilateral right to divorce, and improving the woman's rights to maintenance and control over her dower. Ironically, while each state was able to reform the law of its majority community, for reasons of legitimacy it left the laws governing minorities largely untouched.

In the 1970s, following the independence of Bangladesh, the Pakistani state came to rely more on Islam as a source of legitimacy. General Zia's government introduced the Hudood ordinances, which for the first time in two centuries introduced criminal law based on the shariat. The most controversial provisions dealt with rape, which required four adult male eyewitnesses to establish the charge. If a female victim admitted to sexual intercourse, but was unable to prove that it was rape, she was liable to be sentenced for the offense of *zina* or illicit sex. Despite vociferous opposition from women's groups and human rights organizations the ordinances were not finally repealed until 2006 (Lau, 2007).

The 1970s in India saw the growth of public interest litigation urged on by the Supreme Court. Public interest litigation was marked by the lowering of requirements of *locus standi* allowing various public-spirited persons to appear on behalf of those who could not reach court, the creation of innovative legal remedies including the establishment of monitoring commissions by the court and the *suo moto* taking up of issues by the court. The courts interpreted the constitutional right to life broadly to include the right to food, the right to education, the right to information, the right to health care, and the right to clean environment, creating the basis for new legislation. In many of these cases the courts worked closely with NGOs and social movements, transforming the relationship between law and politics. Public interest litigation doctrines have been readily adopted in Pakistan, Bangladesh, Sri Lanka, and Nepal with the courts bolstering their public legitimacy. Unsurprisingly, judges have emerged as the main site of opposition to governments and the dismissed Chief Justices have led opposition movements in Pakistan and Sri Lanka. More recently, public interest litigation has come under scrutiny for advancing a middle class agenda at the expense of the poor, for instance in ordering slums to be cleared in order to protect a "right to environment" (Narrain and Suresh, 2014).

Conclusion

Divided into several states with political forms ranging from constitutional monarchies, republican democracies, and authoritarian military dictatorships, South Asia legal systems diverged in many ways over the twentieth century. However, certain features remain in common. All systems are marked by widespread legal pluralism and competing legal authorities, including a state-sanctioned system of separate personal laws. With the exception of Nepal, the legal architecture of South Asia, from the court systems to procedural law was largely forged under British colonial rule. The legal codes authored by the colonial state continue to remain in force, with a few postcolonial additions. The Supreme Courts and the higher judiciary of all South Asian states have greatly expanded their powers and authority over the last two decades, emerging as important sites of opposition to government.

The vibrancy of the South Asian constitutional courts stands in stark contrast to the rest of the judicial apparatus. Lower courts remain poorly staffed and marked by corruption and delays. India today has the largest backlog of cases in the world with 30 million cases still pending. The delays are in part due to the colonial origins of procedural laws. Given that the lower judiciary was staffed by Indians whose judgment was never completely trusted by the colonial state, procedural laws retained provisions for appeals at every stage of the trial. As lawyers benefit from the delayed litigation, there has been strong resistance from the legal profession to any attempt to change the procedural laws.

This contrast between higher and lower levels of the legal system leads to a unique situation, where public discourse is marked with the language of law, justice, and constitutionalism while citizens remain cautious about approaching the legal system to settle private disputes.

Abstract

Southeast Asian archaeology runs the gamut from Pleistocene hominin sites to sixteenth-century capitals of the region's first nation-states. This article reviews the origins of modern humans, plant and animal domestication, metallurgy, and urbanism and state society. It discusses theoretical tensions, political concerns, and the future of Southeast Asian archaeology.

Introduction

One might justifiably argue that Southeast Asia as a region is an historical accident that first emerged out of the Supreme Allied Command in Asia in the Second World War. It was first defined as a geopolitical, economic, and sociocultural area, as the 'Southeast Asia Command' in 1943 and included then Ceylon (now Sri Lanka). Today we consider Southeast Asia as a coherent political region that includes the nation-states of the Republic of the Union of Myanmar (Burma), the Kingdom of Thailand, Lao PDR, the Kingdom of Cambodia, the Socialist Republic of Vietnam, Malaysia, the Republic of Singapore, the Republic of Indonesia, East Timor, the Nation of Brunei, the Abode of Peace, and the Republic of the Philippines. Some scholars also include Formosa/Taiwan (Republic of China) and southeast China as part of the region. The region extends *c*.5000 km from its northwest (Myanmar) to its southeastern most point (eastern Indonesia). All of the world's major religions, and hundreds of languages, are spoken in Southeast Asia today, which remains a cultural and linguistic mosaic.

Southeast Asia has a deep archaeological sequence that is broadly divided into the prehistoric and historic periods. Its prehistoric period extends back at least 1.8 million years into the Early Pleistocene; anatomically modern *Homo sapiens* have been reported from sites that date almost as early as 70 000 YBP in both mainland Southeast Asia (Laos; Demeter et al., 2012) and island Southeast Asia (Philippines; Mijares et al., 2010). Early Holocene hunter–gatherers exploited the region's extensive forests and riverine areas; farming was adopted by some, but not all, of the region's inhabitants by the third millennium BCE. Experimentation with copper and alloy technologies began at some point after the mid-second millennium BCE; mainland Southeast Asian archaeologists describe an 'Iron Age' that emerged by the mid-first millennium BCE. Southeast Asia's 'historic' period is associated with the series of polities or city-states across mainland Southeast Asia that shared Indic-influenced ideological systems and cycled in political prominence. While most scholars associate these polities with second millennium CE states like Angkor, Sukhothai, Pagan, and Majapahit, the region's earliest states arose in the mid-first millennium CE in both mainland and island Southeast Asia. Chinese visitors to the region at that time described kingdoms and empires in most places they visited. Islam entered the region with Arab traders in the twelfth and thirteenth centuries. European contact and colonialism in Southeast Asia held elsewhere as a critical hinge point in the archaeological record, marks only the most recent in an unbroken series of cultural encounters that Southeast Asians have experienced.

Almost all of Southeast Asia (except northern Vietnam) lies in the humid and monsoon tropics and experiences abundant rainfall. Its insular (island) region is characterized by geological instability, located as it is on the Ring of Fire. This has created a rich record of seismic, volcanic, and tsunami activity that doubtless left its stamp on human dynamics through time. Mountain ranges and long meandering rivers (notably the Irrawaddy, Chao Phraya, and Mekong) demarcate cultural regions in mainland Southeast Asia: mid-Holocene farmers flocked to the alluvial plains, while upland swidden farmers colonized the uplands of its mountain ranges (Higham, 2002: 83–89). These rivers offered throughways for communication, transportation, and trade; so did the extensive mangrove-fringed coastal zones that flanked the region's seascapes (Indian Ocean, South China Sea, and Java Sea; Spriggs, 2011).

Development of Southeast Asian Archaeology

Southeast Asian archaeology's relatively deep history begins in its region's rulers, who justified their genealogical right to rule through inscriptions as early as the mid-eleventh century. Interest in the Southeast Asian past continued through efforts by mid-nineteenth-century European colonial civil servants who reported ruins and archaeological artifacts. Archaeological practice, in western terms, accompanied European expansion across the region (Higham, 2002: 16–22). During Java's brief British rule (1811–16), Lieutenant Governor-General Thomas Stafford Raffles ordered the investigation and cleaning of the early-ninth-century Borobudur, the world's largest Buddhist monument, which is located in central Java. In the late 1850s, J.W. Earle explored prehistoric coastal shell middens in Wellesley Province, Malaysia. After the tragic death of naturalist Henri Mouhot in 1861, the 1864 publication of his travels up the Mekong and Tonle Sap rivers sparked a European fascination with the vanished Angkorian civilization.

By the late nineteenth century, military men, amateur naturalists, and geologists explored the region's nooks and crannies, and the earliest archaeological institutions were founded. A research officer in archaeology, under the Indian Archaeology Department, was appointed in 1881 in Burma; around the same time, the Dutch East Indies government

appointed archaeologist Willem P. Groenveldt to launch the first systematic investigations of Borobudur. By the turn of the century, the French had established École Française d'Extrême Orient to study monuments across French Indochina; Thai royalty established the Siam Society in 1904 to study its past. Shortly after Emilio Aguinaldo declared the independence of Philippines from Spain in 1898, Americans embarked on their colonial journey and also began exploring the archaeological past and anthropological present of the Philippines.

Late-nineteenth- and early-twentieth-century Southeast Asian archaeology was largely a colonial enterprise; all of Southeast Asia but the Kingdom of Siam was at that time under European colonial rule. Museums and archaeological societies were established by the 1920s across the region, and Southeast Asia' professional archaeologists – including Pieter Vincent van Stein Callenfels, Madeleine Colani, Robert van Heine Geldern, Ivor H.N. Evans, and Otley Beyer – launched major research projects during this time. Geologically oriented scientists explored Southeast Asia's Paleolithic and Neolithic pasts from northern Vietnam to western Indonesia, while art historians, architects, and epigraphers concentrated on its second-millennium CE classical civilizations. Most work was undertaken by foreigners; few non-Anglophone colonials trained local descendants of these ancient cultures in archaeological techniques. The British, in contrast, established an Archaeological Survey of Burma and trained its staff. Americans in the Philippines, under the direction of H. Otley Beyer, established an archaeology training program in the country's first anthropology department at the National University of the Philippines and encouraged the construction of the National Museum. The Far Eastern Prehistory Association formed in Batavia (Jakarta), Java, in 1929 as an offshoot of the Pacific Science Congress (Groslier, 1957); its establishment ushered in the modern era of archaeology in Southeast Asia.

World War II brought Southeast Asian archaeology to a halt for several years, and also transformed Southeast Asia's geopolitics profoundly. One impact of Japan's failed efforts to build its Greater East Asian Co-Prosperity Sphere during the war years was the region's gradual de-colonization. Indonesia declared independence in 1945 and Indonesians took over the Archaeological Service; it took 4 years of struggle before the country gained its liberty. The Philippines was granted independence in 1946, and Burma soon followed. By the mid-1960s, only East Timor remained a colony of Portugal, and later of Indonesia. Archaeological fieldwork accelerated across the region in the 1950s and 1960s. It was not, however, until the 1970s that truly Southeast Asian/western collaborative archaeological research began. Southeast Asian departments of archaeology were established, and so was the region's first archaeological journal, *Asian Perspectives* (editor: Wilhelm Solheim), in 1957. Southeast Asian archaeologists like U Aung Thaw (Archaeological Survey of Burma) began to publish monographs on their research and assume leadership roles in the field. Some foreign archaeologists (like Wilhelm Solheim and Chester Gorman) worked closely with Thai colleagues on their field-based research. Their work and that of many others put Southeast Asian archaeology on the world's stage. The establishment of SEAMEO ARCAFA (Southeast Asian Ministers of Education Organization Applied Research Centre for Archaeology and Fine Arts) in 1971 and subsequent launch of SPAFA (SEAMEO Project in Archaeology and Fine Arts) in Bangkok signaled the first significant entry of Southeast Asians into the archaeological research world.

More than a decade into the twenty-first century, Southeast Asian archaeology hardly resembles its predecessor from the pre-World War II years. Trained professional archaeologists work in every Southeast Asian country on prehistoric and historic period sites; most countries have heritage management ministries or bureaus that conserve (largely architectural, but some prehistoric) archaeological sites and manage visitation; every country offers undergraduate training in archaeology; and at least three countries, the Philippines, Vietnam, and Malaysia, offer PhD degrees in the field. Western archaeologists work closely with their in-country colleagues, and international, multidisciplinary teams are a regular feature on the archaeological landscape of island and mainland Southeast Asia. The following section outlines general findings from the Pleistocene through late Holocene periods, which covers biological developments like the emergence of modern humans and political developments like the emergence of states and empires.

From Pleistocene Hominins to Early States

Early Hominin Occupation of Southeast Asia

Eugene Dubois, a colonial Dutch Army medical officer, first uncovered evidence for Southeast Asia's Pleistocene hominin record when his prisoner field crew uncovered remains of what became known as *Pithecanthropus erectus* (now known as *Homo erectus*) along the banks of the Solo River, Java, in 1891. His European colleagues received this news coolly during Dubois' postdiscovery tour to report this 'the missing link' between apes and humans. It took several decades for the scientific community to accept that the Javanese fossils belonged to a human ancestor, and we now believe the 'Trinil 2' cranial fragment dates before 800 000 YBP. One of many discoveries reported from the region, most scholars now agree that *H. erectus* populations roamed the region by the Middle Pleistocene, and some assert an initial occupation beginning by *c.*1.8 million YBP.

Southeast Asian evidence for Middle Pleistocene hominins and their behavior concentrates in Java, although scholars have reported material from both island and mainland of Southeast Asia. Predominant tool types in associated lithic assemblages (pebble and flake tools) contrast markedly with the Acheulian hand axe industries that characterize African, European, and now South Asian *H. erectus* populations. Whether this difference in patterning reflects raw material availability remains debated, but what distinguishes Southeast Asia's record is unequivocal evidence for maritime voyaging capability that enabled Middle Pleistocene hominins to reach Flores Island (and cross a deep-water trench) by *c.*880 000 years YBP. Crossing this deep sea channel that was not connected to Sundaland (the biogeographical region of Southeast Asia that included current-day Borneo, Sumatra, Java, and mainland Southeast Asia) at any point during the Pleistocene required sophisticated cognitive abilities. Just how they reached Southeast Asia initially also remains an issue of some debate:

a coastal route (from South Asia) and an East Vietnam route, originating in southern China, are both possibilities.

Consensus now holds that anatomically modern humans dispersed out of Africa during the Late Pleistocene, after 125 000 YBP, and ultimately into Southeast Asia. Deciding how Southeast Asian hominins fit into competing scenarios of modern human origins (i.e., whether modern humans evolved somewhat independently in multiple locations where Middle Pleistocene hominins have been found (the regional model) or whether modern humans originated in Africa and dispersed outward in the (the replacement model)) requires us to examine the earliest evidence for modern humans in the region (*c*.70 000 YBP (Mijares et al., 2010)) and factors that may have constrained or encouraged migrations (*see* Demographic Impact of Disasters; Migrations, Colonizations, and Diasporas in Archaeology). Southeast Asia's well-dated super-eruption near Lake Toba in Sumatra, Indonesia *c*.74 000 YBP exerted global climatic effects; whether Toba's eruption created a genetic bottleneck (in which most extant human populations perished) remains a matter of debate. Current research on the time period in South Asia suggests that Paleolithic hominins survived these catastrophic fluctuations, but a current paucity of Southeast Asian sites that date between 90 and 70 000 YBP hampers our understanding of developments.

Disagreement continues over the taxonomic status of *Homo floresiensis*, a small hominin that produced stone tools and has been recovered from Liang Bua cave on the Indonesian island of Flores. Researchers agree that the fossils date to *c*.18 000 YBP, but debate continues over whether the *Homo* fossils represent a distinct hominin species (ostensibly descended from *H. erectus* or another earlier hominin) or instead a pathological pygmy population of modern *H. sapiens*.

Late Pleistocene/Early Holocene Hunter–Gatherers

Scholars have now reported dates from many Pleistocene sites beyond Java that predate 40 000 YBP, but the strongest signature for modern humans in Southeast Asia begins at this time. Cave sites have been documented in southern Thailand (Tham Long Rongrien), the Philippines (Tabon Cave), Borneo Island (Niah Cave), and eastern Indonesia (Leang Burung 2). Foragers who occupied these sites are associated with either flake or pebble/cobble tool assemblages; they practiced broad-spectrum subsistence that included terrestrial fauna (bovids, land tortoises, pigs, non-human primates, rodents), mollusks (freshwater fishes and shellfish), and sessile (immobile) coastal resources like mussels (*see* Hunting and Gathering Societies, Anthropology).

The number of sites dating after 15 000 YBP is now robust. Early Holocene foragers occupied maritime and riverine settings in lowland Southeast Asia. They left shell middens along waterways, worked upland areas for mammalian resources (e.g., deer, pigs, and monkeys; Higham, 2002: 46–49), and may have managed tree nut crops (canarium). We know the most about Late Pleistocene/Early Holocene populations associated with the Hoabinhian tool tradition represented by 'sumatraliths': stone tools, worked on one side, that are found across mainland Southeast Asia and as far south as Sumatra. Hoabinhian occupation has been documented in open-air and cave sites (Forestier et al., 2013) and include residential and mortuary sites (Zeitoun et al., 2013). Pebble tools, bone points, and antler wedges were also part of this industry; grinding stones have been identified in the latest Hoabinhian occupations.

Early to mid-Holocene foragers buried their dead with ocher, stone tools, and animal bones (Zeitoun et al., 2013). Substantial research has focused on determining whether the 'Hoabinhian' were the original settlers of mainland Southeast Asia and deciphering their relationship to extant indigenous (Negrito) communities across the region today. Some physical anthropologists associate well-dated Hoabinhian skeletal remains with 'Australo-Melanesian' populations; some Vietnamese and Thai sites contain 'Neolithic' phases superimposed atop Hoabhinian phases, and the Da But culture of northern Vietnam (Nguyen, 2005) contains evidence for intensive plant and animal use that could represent a transition to agriculture by indigenous inhabitants.

Defining the nature of Southeast Asia's earliest plant and animal domestication remains a subject of great scholarly interest. Archaeologists disagree over whether migrants entered the region with a suite of agricultural knowledge and displaced the extant foragers (whose descendants are today's Negrito populations), or whether Late Holocene foragers gradually intensified resource use until they became reliant on plant and animal domestication for subsistence (Bellwood, 2006). At issue is how this mid-Holocene plant and animal management system articulated with extant human groups in the region, and whether it coincided with a rapid population infusion of Austroasiatic speakers into the densely populated south China (*see* Language Families, Archeology and History of; Migrations, Colonizations, and Diasporas in Archaeology). If the latter process occurred, it may have been considerably more complex than is currently envisioned (Spriggs, 2011); it also may have generated 'friction zones' that held both intrusive farmers and indigenous foragers (e.g., Higham et al., 2011). Some may have intermarried, others colonized the region, and still others continued their southward journey into the Pacific. Archaeologists also argue over the nature and tempo of the process of plant and animal domestication across a region whose Neolithic cultivation regimens included both agriculture (rice, millet) and vegeculture (at least taro, and perhaps yams; *see* Horticultural Societies; Food Production, Origins of). Reasonable consensus exists, however, that Southeast Asia, writ large enough to include areas south of the Yangzi River, was the hearth/origin area for several key plant domesticates (most notably rice, yams, taro, and spices like nutmeg and mace) and animal domesticates (most notably dogs, pigs, chickens, and water buffalo).

Archaeologists also agree that some, if not all, mainland Southeast Asians practiced grain-based agriculture no later than 4000 YBP, and that their island Southeast neighbors embraced cultivation regimens a millennium after that (Amano et al., 2013). Vietnam's archaeological record for this mid- to late-Holocene transition is the most robust in the region and dates to *c*.4000 BP or earlier. The recently reported An Son site of southern Vietnam offers an excellent example of Neolithic Southeast Asia, with incised and impressed earthenware pottery, groundstone adzes and axes, fishhooks, beads, and a faunal assemblage that suggests riverine farming economy that was supplemented by dog and pig domestication (Bellwood et al., 2011).

Early Farming Communities

Archaeologists who routinely describe Southeast Asia's 'Neolithic' struggle to reconcile its material signatures with that found in the Near East or Europe (e.g., Bellwood, 2006). Southeast Asians added cultivation and earthenware ceramic technology to their foraging regimens between 4500 and 3500 years ago, but only slim evidence has been found for a monolithic shift to the kind of sedentary, village-based tribal organization that characterizes the Neolithic in other Old World regions. Limited archaeological evidence suggests that sprawling alluvial plains across the region's mainland and the insular zones' narrow river valleys housed growing cultivator populations. So did coastal and upland regions. All used polished or groundstone technology (particularly stone adzes and chisels, and groundstone bangles), cleared forests, and engaged in broad-spectrum subsistence regimens that included wild and cultivated resources (see review in Higham, 2002: 83–111).

Thailand's central and northeastern regions have yielded Neolithic sites that offer a glimpse of village-based farming life. Some archaeologists contend that craft specialization (like pottery production and/or shell adze production) and intercommunity exchange characterized these early communities like Khok Phanom Di (Bentley et al., 2007; *see* Craft Production, Anthropology of). Few well-dated Neolithic sites contain substantial skeletal and mortuary data. Southeast Asian archaeologists continue to devote more energy to tracing potential migratory routes of humans and their *Oryza sativa japonica* rice into the region than to exploring the nature of settlement or subsistence during this crucial period of time. Recovery of obsidian from shared sources (Reepmeyer et al., 2011), similar or identical artifact types, and a broad incised pottery stylistic horizon suggests that these 'Neolithic' communities engaged in large-scale interactional networks that stretched from Formosa into Sulawesi.

The Southeast Asian 'agricultural package' of rice, pottery, and sedentism arrived substantially later in parts of island Southeast Asia, and assumed different forms as the knowledge moved east toward Papua New Guinea (*see* Australia and New Guinea, Archaeology of). Borneo's 'Neolithic' peoples may have relied on sago rather than rice (Barton, 2012); in eastern Indonesia, sago was the carbohydrate staple. Direct evidence of plant domestication is scarce. Paleoenvironmental studies suggest that Sumatra's forests were impacted as early as 6400 YBP, and permanently cleared after 3000 YBP. Cave and rock shelter sites across island Southeast Asia offer evidence of pottery and rice *c*.4000 YBP, and burials associated with stone adzes, bone points, shell bangles, and incised earthenware indicate agricultural practices.

The Earliest Metal Age

Geopolitics and historical accident has skewed western knowledge of the Southeast Asian Bronze Age archaeological record toward Thailand, with recent research incursions into Myanmar and Cambodia. Mainland Southeast Asians engaged in copper and bronze metallurgical production and distribution by the mid to late second millennium BCE. Scholars continue to debate origin areas and transmission routes for bronze metallurgical knowledge (White and Hamilton, 2009). Northern Vietnam's Phung Nguyen culture (*c*.4000–3500 YBP) displays the earliest well-dated bronze metallurgy in the region. Within a few 100 years, metal workers in central and NE Thailand melted crushed copper ore into crucibles and cast this into stone and ceramic molds to create vessels that moved along riverine and coastal distributional networks.

Archaeologists have studied Mainland Southeast Asia's Metal Age (i.e., the 'Bronze Age' (sensu Higham, 1996) and the 'Iron Age') more intensively than any other prehistoric period, and Thai and Vietnamese sites have gotten the most attention. Most Metal Age sites are mortuary. They have yielded copper ingots, socketed ax heads, chisels, arrow and spear points, fishhooks, and sickles, and bioarchaeological approaches dominate the literature (*see* Bioarchaeology). The limited attention to regional-scale Metal Age settlement organization, using Thai survey and excavation data, suggests both the development of village-based specialization and subregional variability in production and distribution of metal objects (but see Eyre, 2011; *see* Intensification and Specialization, Archaeology of). Island Southeast Asia entered the Metal Age as much as 1500 years after mainland Southeast Asia. Sites proliferated across this southern region after the appearance of 'Iron Age' manifestations on the mainland.

Southeast Asia's Early Complex Polities and the 'Iron Age'

The earliest incontrovertible trappings of 'social complexity' (i.e., institutionalized stratification, intercommunity competition and conflict, a prestige goods economy; *see* States and Civilizations, Archaeology of) appeared all over Southeast Asia *c*.2500 YBP, which in the mainland is associated with the 'Iron Age.' It is during this time that the first localized metallurgical traditions, elaborate mortuary rituals, settlement hierarchies, and widespread stylistic horizons reflecting far-flung elite exchange networks became well established. Out of densely populated northern Vietnam, and arguably SW China (Yunnan and Guizhou Provinces today), emanated a bronze drum tradition whose use in collective ceremonies (still seen in some ethnohistorical upland groups) bore the signatures of complex societies. Bronze drum iconography – particularly from the Lake Dian drums of SW China – reflect shared ideological traditions, collective action, and possibly conflict (Higham, 1996). Vietnamese archaeologists have explored Iron Age sites across the Bac Bo region rather thoroughly, documenting settlement and mortuary sites. Geochemical studies suggest that nephrite (jade) artifacts were manufactured and traded from Formosa throughout central Vietnam and the central Philippines (Hung et al., 2007). Dong son bronze drums from northern Vietnam have been found as far south as Java and across much of mainland Southeast Asia.

Most research on Southeast Asia's Iron Age concentrates on human remains from cemeteries that contain, to varying degrees, markers of interpersonal violence and are associated with abundant bronze and iron weapons (e.g., Domett et al., 2011); these sites signal the rise of competitive polities. Some Southeast Asian populations lived along the southern fringes of the Han imperial world: these 'southern barbarians' resisted conquest everywhere but northern Vietnam. Most participated

in, and many were affected by, maritime silk trade that sliced through the region to link China with South Asia (Bellina and Glover, 2004). Island Southeast Asia's Metal Age was also, temporally speaking, the Iron Age since Island Southeast Asia lacked a preceding Bronze Age. Mainland Southeast Asia's endpoint of the Iron Age lacks a clear temporal boundary, although most archaeologists concur that the period between 2000 and 1500 BP marked the transition to history, and the appearance of the region's first indigenous writing systems, influenced largely by South Asian predecessor scripts (*see* Historical Archaeology).

Early States

The earliest archaeologically visible states arose during that transition to history across the river valleys and along the coasts of Mainland Southeast Asia from northern and central Vietnam (Allard, 1998; Southworth, 2004) to Thailand and Malaysia (Allen, 1998); they also emerged along Sumatra's coasts. Described and assigned toponyms by visiting Chinese emissaries, these city-states (Manguin, 2004) and coastal chiefdoms (Junker, 2004; *see* Chiefdoms, Archaeology of) formed a complex network of deep-water ports and entrepôts for goods that moved through the South China Sea toward both South Asia and the Mediterranean, and in the reverse direction to China. The region's earliest states varied in size and geographic extent. Most bore the influence of Buddhist and Hindu ideological systems that entered the region with trade and that sculpted ritual landscapes of Indic-influenced shrines, temples, and nucleated communities (Stark, 2006; *see* States and Civilizations, Archaeology of).

Southeast Asians' involvement in this dynamic world-system brought them wealth and non-local goods that facilitated the rise of landed elites and the legitimation of centralized authority, virtually all within a new ideological system from South Asia with roots in Brahmanic belief systems. Intensified interregional interaction and movement across the Bay of Bengal also generated an increasingly complex regional organization. Large centers, ruled by 'Hinduized' elite, rose and fell through time within large regions. The Pyu 'city-states' arose along and beyond the Irrawaddy River through Myanmar's central Dry Zone to the west; Dvaravati settlements flanked the receding Bay of Bangkok in central Thailand, and snaked to the northeast along the Chao Phraya river and its larger tributaries. Hinduized pre-Angkorian polities populated the lower Mekong region, expanding out from the preceding period through the construction of ashrams, shrines, temples, and large centers. The pre-Angkorian epigraphic record offers rich insights on the states of the late first millennium CE: their elites garnered power through ritual sponsorship, channeled resources through their community temple foundations, and participated with their followers in ritual practice that circumscribed their agricultural cycles and shaped their political lives (Higham, 2002: 298–335; Stark, 2004).

Most of these late first millennium polities have clear archaeological antecedents that date to the period from 2500 to 1500 YBP (Stark, 2006). Some Cham sites in central Vietnam sit directly atop Iron Age Sa Huynh archaeological sites; pre-Angkorian sites have underlying 'Funan' deposits from the first through fifth centuries CE, and Myanmar's Pagan has Pyu finger-marked bricks from the second century BCE to the eighth century CE (Hudson et al., 2001). Today's Southeast Asian nation-states trace their roots back to the classical states associated with the ninth through fifteenth centuries CE: Bagan (in Myanmar), Sukhothai and Ayutthaya (in Thailand), Angkor (in Cambodia), and Champa and Dai Viet (in Vietnam). Archaeologists can now assert, with some certainty, that these classical states have roots that extend backward in time to the region's first states. Until rather recently, art historians and historians have dominated research agendas on the ninth through fifteenth century states, whose monuments are major tourist destinations that are managed by cultural heritage agencies. The last three decades has seen a surge of archaeological interest in these states. For historical and logistical reasons, more field investigations have concentrated at Cambodia's Greater Angkor region than any other classical capital in the region (e.g., Evans et al., 2007). Increased attention to other late capitals offers rich comparative data for archaeologists who study the collapse and regeneration of premodern states.

Theoretical Tensions and Political Concerns in Southeast Asian Archaeology

Theoretical tensions shape the research directions of Southeast Asian archaeology and affect its practitioners. Artificial divides within and beyond archaeology hinder forward progress: 'prehistoric' and 'historic' archaeologists rarely communicate, and the latter struggle to reconcile art historical and documentary evidence with archaeological patterns. Some archaeologists are theoretical purists, using approaches from western academe (*see* Archaeology, Theory in) while others practice some form of culture history. Most scholars bifurcate into 'endogenous' and 'exogenous' camps to explain most origins: of modern humans, of food production, of metallurgy, of urbanism, and of states. Staunch proponents of each extreme ignore empirical findings and bolster their claims; those in the middle struggle to reconcile archaeological patterning with preconceived models developed elsewhere, for other archaeological records.

Archaeologists apply increasingly sophisticated methods to Southeast Asia's archaeological record, but it continues to resist categorization. Modern humans entered the region, but coexisted with small hominins (or hobbits) until the late Pleistocene. Populations adopted rice from Southeast China, but did not shift to a reliance on agriculture until many centuries later, in the Bronze Age (King et al., 2014). Urbanism and state-level society emerged in concert with 'Hindicization' in mainland Southeast Asia, but most of Island Southeast Asia remained free of cities despite their embrace of Indic ideas. Rulers called themselves *cakravartin* (universal ruler (Sanskrit)), yet ruled at the pleasure of their followers as their ephemeral polities rose and collapsed in regular succession. Respecting Southeast Asia's archaeological record for its own sake, rather than forcing it into extant models, takes great effort.

Southeast Asian archaeologists increasingly acknowledge the effect of political concerns on archaeological practice. Until recently, western-born (or at least western-trained) archaeologists set the agenda. As growing numbers of Southeast Asian nationals become archaeologists, discussions grow over

whether to follow western intellectual paradigms or their indigenous archaeological frameworks. Some countries, like Malaysia, not only train their own archaeologists, they restrict foreigner access to their archaeological resources (*see* Archaeology, Politics of). Others (Thailand, Philippines, Cambodia, and, increasingly, Vietnam) welcome international collaboration that includes capacity building for the next generation. Achieving parity in the Southeast Asian archaeological community is challenging, since most trained Southeast Asian archaeologists work in heritage management rather than in academia (*see* Cultural Resource Management: Conservation of Cultural Heritage).

Future Research Directions for Southeast Asian Archaeology

More Southeast Asian archaeologists today practice their trade than at any time in the region's very deep history. They study vastly different time periods, embrace radically different epistemologies, investigate myriad topics, use cutting-edge technologies, and report their work in more than 10 languages. Southeast Asia's archaeologists are cataloging the cultural and ecological mosaic as rapidly as possible. Archaeologists remain one step ahead of economic transformations that threaten the region's precious archaeological record. Future directions for Southeast Asia's archaeologists involve every period under study, and every ecological zone in the region. Southeast Asia contains karst limestone caves with Pleistocene deposits and speleothems that warrant attention before they are destroyed for construction materials. Southeast Asia's shell middens and mid-Holocene sites must be studied before rising sea levels eradicate them. Work is needed on settlement organization and habitation patterns to complement the rich and informative mortuary database available on the Neolithic, Bronze, and Iron Ages. Researchers could maximize the information potential of extant museum collections and by studying geochemical patterning in trade wares that circumscribed some states like Angkor, and that linked others through maritime trade, like Sukhothai. The region's sixteenth through nineteenth century past, which holds insights on the Early Modern period, is undergoing urbanization. The world grows closer each decade, and the future holds great potential for international collaboration in Southeast Asian archaeology.

Southeast Asia: Sociocultural Aspects

Hans-Dieter Evers, Universiti Brunei Darussalam, Brunei Darussalam

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Southeast Asia is a very diverse region in terms of societies, languages, and cultures. Pluralism, loose structure, and highly ritualized political systems have been identified as typically Southeast Asian. Boundaries between ethnic groups are blurred, and ethnic classifications vary. Religious diversity has been increased by external religious movements and fundamentalist Buddhism, Christianity, and Islam. Social class formation has produced an increasing gap between the rich and the poor, as well as ethnic clientelism and power struggles between strategic groups. Strategies to develop a knowledge-based economy are widely followed to achieve developed-nation status.

The Sociocultural Construction of Southeast Asia

Conceptualizing Southeast Asia

Southeast Asia includes the Association of Southeast Asian Nations (ASEAN) states of Brunei, Indonesia, Malaysia, the Philippines, Singapore, Myanmar, Thailand, Cambodia, Laos, Vietnam, and East Timor. Despite its extreme diversity in terms of population density, ethnic groupings, religion, politics, and economic development, the area has common characteristics, many of which are constructed by social scientists and politicians and are increasingly recognized (King, 2008, pp. 15–17). In addition to the nation-building efforts of individual governments, a common Southeast Asian identity has emerged, at least in the urban middle classes.

Southeast Asia has undergone a multitude of crises, economic, political, cultural, and social. Most of these have resulted in a fresh look at what courses Southeast Asian societies have taken, and what concepts and theories can be used to analyze new developments. As a matter of fact, some of the new concepts and paradigms have been exported to other world regions, utilized and generalized and entered into the realm of general theory, while their procreators and their region of origin have often been forgotten. Dualism, plural societies, involution, strategic groups, and loosely structured social systems are by now standard terms in social science research, although originally they were empirically based concepts used to describe Southeast Asian social conditions.

What we now call Southeast Asia has gone through a series of cycles of the social and political construction of the region. As Said (1978, p. 5) has rightly asserted, "geographical and cultural entities … are man-made." Localities are not given, but are socially constructed. To mention just a few terms that over time have signified different external and internal efforts to construct a more or less unified image of the area: the 'Golden Chersonese' of Ptolemy, Further-India, Hinterindien, Extrême Orient, Nusantara, the Greater Co-Prosperity Sphere, French Indo-China, Pacific Asia, Southeast Asia, and, more recently, ASEAN.

Indianization and Islamization

The term Southeast Asia became common usage only during and after World War II. Before, the area was seen as culturally colonized by its large neighbors, India and China. Coedès (1968, pp. 15–16) described the classical states as États Hindouisés, or 'Indianized states,' and further stated, "Indianization must be understood as the expansion of an organized culture that was founded upon the Indian conception of royalty, was characterized by Hindu or Buddhist cults, the mythology of the *Purānas*, the observance of the *Dharmaśāstras*, and that expressed itself in the Sanskrit language. Far from being destroyed by the conquerors, the native peoples of Southeast Asia found in Indian society, transplanted and modified, a framework within which their societies could be integrated and developed." This marriage of Austronesian and other local cultures with Indian patterns of sociocultural organization has remained a common background, on which later Chinese, Muslim, and European influences have been grafted. The Balinese and several smaller societies, such as the Tengger, maintain the Hindu tradition.

Islam came to Southeast Asia probably as early as the eighth century AD, but became a major force of social and political change only from the fourteenth century onward. The creation first of a trading and religious elite, then of a political elite through conversion, introduced a new element into the coastal states of Southeast Asia along the straits of Malacca, the northern coast of Java, Sulawesi, and the Moluccas. The process of Islamization is a still-ongoing process.

Religious Diversity and Religious Revivalism

In addition to animistic beliefs and related belief systems, most major world religions are found in Southeast Asia. Indonesia, Brunei, and Malaysia together have the largest Muslim population worldwide. The majority of the population of Myanmar, Thailand, Cambodia, and Laos adheres to Theravada Buddhism, the Philippines has a majority of Christians; and Singapore and Vietnam are characterized by a multitude of religious beliefs often cutting across family and kinship lines, although Confucian ideals are also widespread.

During the second half of the twentieth century, religious revivalist movements swept through most of Southeast Asia. In Thailand, middle class–based religious organizations have preached a return to Buddhist values (Tambiah, 1976). The Javanese mystical tradition has influenced Muslim brotherhoods or led to the foundation of mystical sects: *aliran kebatinan*,

 http://dx.doi.org/10.1016/B978-0-08-097086-8.12020-3

Subud, and others (Geels, 1997; Lombard, 1990). The Singapore government has propagated Confucian values, while Christian sects have proliferated and found new adherents among students and young upwardly mobile employees.

In Malaysia, a missionary movement (*dakwah*) has led to a resurgence of Islamic practices, especially in the eastern coastal states of Kelantan and Trengganu. Fundamentalist Islamic thought, backed by Saudi Arabian Wahhabi influences, has led to a growth of restrictive practices, especially for women; the introduction of sharia law in some states; and the growth of terrorist organizations. Islamic revivalism is strong in Malaysia and southern Thailand, and is gaining strength in Indonesia, which has become the largest Muslim country worldwide (Houben, 2003). Brunei Darussalam is still a traditional sultanate, following a state ideology of a Malay Muslim kingdom (Hussainmiya, 1995).

Ethnic Diversity

Boundaries between ethnic groups are blurred, and there are differences between self-interpretation and ethnic classifications imposed by others. In Singapore, the population is officially classified into Chinese, Indians, Malays, and others (usually identified as Eurasians and Caucasians), although there are many more self-ascribed categories. The Malaysian government distinguishes between *bumiputra* (sons of the soil) and immigrants, but there are also *Orang Asli* (aborigines), Indians, and Chinese. People of Arab descent are no longer seen officially as a separate group, but in Indonesia, the culture, legal system, and language of larger ethnic groups such as the Javanese, Balinese, Batak, Minangkabau, and many others are recognized and expressed in cultural, although not political, terms. In Thailand, Laos, Myanmar, and Vietnam, the lowland population is distinguished from 'hill tribes,' an ethnically and linguistically diverse population. The difference between a lowland, rice-growing peasant society and nonsedentary 'tribal groups' practicing shifting agriculture has been emphasized but is disappearing slowly due to assimilation or replacement.

The peoples of Southeast Asia have also been classified along linguistic lines. Despite recent criticism, the classification into Sino-Tibetan, Austro-Asiatic, Tai-Kadai, and Malayo-Polynesian is still widely used (LeBar et al., 1964, 1972). In most countries or regions, we can distinguish one dominant lowland society and several upland satellite ones. Anthropological and sociological research has enriched our knowledge of the major societies that have been politically dominant in the formation of pre- and postcolonial states, and also the large number of smaller societies from the hunter-and-gatherer societies, like the *Orang Asli* groups in Malaysia, to larger groups, like the Shan and Kachin in Myanmar (Leach, 1954); the various hill tribes of Thailand, Laos, and Vietnam (Kunstadter, 1967); or the matrilineal Minangkabau of west Sumatra (Kahn, 1993).

Plural Societies

The in-migration of Arab, Chinese, and South Asian migrants in the wake of the expansion of a colonial economy has created what Furnivall termed a plural society, "with different sections of the community living side by side, but separately, within the same political unit" (Furnivall, 1948, p. 304). This ethnic pluralism was transcribed into colonial and postcolonial administrative practice, giving rise to a classification of the population into Chinese, Malay, Indian, and others in colonial and contemporary Singapore or into indigenous Malays as 'sons of the soil' (*bumiputra*) and migrant communities in Malaysia. Thailand, in contrast, has followed a policy of assimilation, in which all minorities are classified as Thai, whereas in Indonesia the Javanese dominance is balanced precariously by allowing the construction of ethnic, but not political, pluralism in the form of the cultural symbolism of local art forms and dances. With the exception of Singapore, one common national language has been introduced and enforced with varying degrees of acceptance and use in all Southeast Asian states.

Moral Economy

Geertz and others have underestimated the dynamics of Southeast Asian peasant societies. Rebellions and peasant uprisings have continued well into the twenty-first century (e.g., in Aceh and East Timor). The "moral economy of the peasant," illustrated by Scott (1976) with reference to Vietnamese and Burmese societies, indicates that a subsistence ethic governs peasant behavior. Only if the self-defined subsistence level is threatened, have peasants rebelled.

The moral economy also governs petty trade in the informal sector of most of Southeast Asia. The moral obligation of sharing work (*gotong royong* in Indonesia) and profits puts a burden on small traders, mostly women, who find it difficult to accumulate profits to sustain and expand their trading enterprises. There are, however, solutions to this 'trader's dilemma' (Evers and Schrader, 1994): where indigenous traders fail, immigrant trading minorities like the Chinese take over the business. Otherwise, the indigenous traders themselves improve their moral status by forming or joining religious fundamentalist movements, like the Santri traders of Indonesia, to escape the pressure of moral obligations. Often, trade is carried out on a subsistence level, as in the case of female petty traders, where the obligation to share meager profits does not arise because no cash is accumulated.

The informal sector of small handicraft production, petty trade, and other services is widespread in Southeast Asia (Evers and Schrader, 1994) and has increased in Vietnam during the transformation from a planned socialist economy to a more market-oriented economy, but it has declined in Singapore and Malaysia. This sector is playing an important role in cushioning the effects of land shortage in Southeast Asia's rice-growing areas, of rural–urban migration, and of a general lack of social security provisions.

Big Men and Theater States

The further one proceeds southeast through Indonesia and the Philippines, the more evident the Austronesian-Melanesian-Polynesian content of Southeast Asian culture becomes. Wolters (1982) has drawn attention to the 'big man' phenomenon, which he locates in Polynesia. The current emphasis on personal prowess, the power of the oratory, and admiration for superiors and leaders is put into this context. The state and its aristocratic

bureaucracy are admired as much in Thailand as in Malaysia, Brunei, or Indonesia.

The state in these countries is highly ritualized and has been named a 'theater state,' following Geertz's analysis of the precolonial Balinese states (Geertz, 1980). In earlier times, the state was largely a performance with little administrative or military power. It is debatable whether this analysis withstands the test of historical data, but at least the theme of vagueness, looseness, involution, and theatricality in some Southeast Asian societies pervades the anthropological literature.

Loosely Structured Social Systems and Involution

John Embree once classified Thai society as 'loosely structured,' thus igniting a long-drawn controversy among social scientists (Evers, 1980, pp. 163–198). Thai society has a cognatic kinship system, a shallow recognition of descent, and a high degree of individualism, but a highly regulated 'bureaucratic polity' and a tendency to form cliques and patronage. Another, equally unconvincing attempt at using single cultural traits or selected ethnographic details has stressed dualism as a common characteristic of Southeast Asian societies. There was a greater acceptance of the work of Geertz, who classified Javanese society as "involuted," by "overdriving of an established form in such a way that it becomes rigid through inward over elaboration of detail" (Geertz, 1963, p. 82). This process applied mainly to wet rice agriculture and its tenancy system, but was also seen at work by other scholars in other regions like the Philippines or Thailand, or in the relatively slow process of Southeast Asian urbanization up to the middle of the twentieth century (Evers and Korff, 2000).

Contemporary Southeast Asian Studies

Diasporas and Business Networks

Migrant communities, like the Overseas Chinese originating from southern China, the South Indian Chettiar, or the Hadramaut Arabs, have been classified as trading minorities in view of their economic position in Southeast Asian societies. Others migrated to Southeast Asia in large numbers at the beginning of the twentieth century to work in plantations, mines, and the construction sector. Chinese business has been studied in great detail. Singapore has become the center of the Chinese business community (Chan and Chiang, 1994; Menkhoff and Gerke, 2000). Confucian ethics, patrilineal kinship–based networks, and the patriarchal organization of family firms have been held responsible for economic success and the predominance of the Nanyang Chinese. Prosecution, discrimination, and conflict have strained interethnic relations in Malaysia, Indonesia, and Vietnam.

Social Class and Strategic Group Formation

Colonial Southeast Asian societies were "moulded on racial principles: belonging to the dominant white upper caste provided one with prestige and power largely independent of one's personal capabilities. A strict ritual was introduced and maintained, by force when necessary, to preserve the white caste from contacts with Asiatics on a basis of equality and to maintain the former's prestige as the dominant group" (Wertheim, 1968, p. 432).

In the course of decolonization and modernization, Southeast Asian societies have undergone a process of class formation (Evers, 1966, 1973, pp. 108–131; King, 2008, pp. 98–128). The colonial upper classes were replaced by ethnically differentiated elites, in which indigenous aristocrats, Chinese and European business people, and the upper ranks of a fast-growing bureaucracy and military officers played a major role. The concept of a strategic group can be used to analyze this new situation more adequately. The pattern of strategic group formation differed from country to country. In Thailand, which had escaped the fate of colonialism, the growing bureaucracy, backed by sections of the military, revolted against the aristocracy and replaced the absolute monarchy in 1932 with a new regime, in which the strategic group of the military gained the upper hand, until a growing group of professionals, university lecturers, and students managed to establish a democratic government. Strategic group conflict continued, mediated by the electoral process, and put big business into power in 2001. Similar strategic group conflicts, rather than class struggle, signified the situation in most countries, except perhaps in the socialist states of Vietnam and Laos, where party cadres, another strategic group, maintained power after the communist victory in the Vietnam War (Evers and Benedikter, 2009). The partial reprivatization of land and the deregulation of the economy introduced, however, new social processes, from rural–urban migration to corruption of government officials and the formation of a group of newly rich businessmen.

Class formation moved ahead, and the growth of a middle class became a much-researched topic in Southeast Asia (Robison and Goodman, 1996; Gerke, 2000; Embong, 2002). The growth of a new middle class was seen as a basic requirement for democratization and the building of a civil society. Whereas in Thailand, the Philippines, and Indonesia, a civil society with a proliferation of nongovernment organizations developed and pressed successfully for reformation and the introduction of democracy, the prodemocracy movement met with some success from 2011 in Myanmar, although a strategic group of military officers remained in power.

A working class emerged first through the development of plantations and mining, and later through industrialization (Ibrahim, 1998; Evers, 1966). Throughout Southeast Asia, the fruits of rapid development became during the new millennium increasingly concentrated in a super-rich upper class of business tycoons and more or less corrupt government officials and land speculators.

The middle classes have developed a special lifestyle of their own that blends Western consumerism with elements of Asian modes of living. Hawker centers, food courts, and open-air markets exist alongside big department stores, pizza parlors, and hamburger outlets. The anthropology of Southeast Asian food has to be concerned with syncretism and lifestyling as much as with religious symbolism.

Along with the demand for consumer goods, the demand for knowledge has also increased. In fact, the ASEAN (Association of Southeast Asian Nations) region has undergone a tremendous expansion of higher education. In the core states of Thailand,

Malaysia, Singapore, the Philippines, and Indonesia, the number of students and teachers, and of secondary schools, colleges, and universities, have risen dramatically. Malaysia and Singapore, in particular, are on their way to becoming knowledge societies, where economic and social development is increasingly knowledge driven. Most ASEAN leaders and governments have developed visions of the future that target a knowledge society as a way to achieve parity with the Western world. This vision is but one in a long line of ideas on how Southeast Asia should be seen, interpreted, and eventually constructed.

Family and Gender Relations

The small nuclear family is widespread, or has become the norm more recently, as in Vietnam (Pham Van Bich, 1999) or among Singapore Chinese. The position of women has been regarded as strong throughout Southeast Asia (Watson-Andaya, 2007), in particular in matrilineal societies like the Minangkabau (Kahn, 1993). Demographic changes and the decline of fertility due to family planning have strengthened the position of women in Thailand, Vietnam, and Indonesia, giving them greater control over their own lives (Gerke, 1992; Barry, 1996). Industrialization and the employment of female factory workers, especially in the garment and electronics industries, have led not only to migration and chances for educational attainment but also to exploitation and harassment of women (Sen and Stivens, 1998).

Globalization, Urbanization, and Locality

Right into the 1980s, Southeast Asia, except for the city-state of Singapore, showed only relatively low rates of urbanization (Evers, 2011). Since then, urbanization has taken off, creating large urban conglomerates like the greater Bangkok area, Jabotabek (Jakarta, Bogor, Tanggerang, and Bekasi), the Manila metropolitan area, and the Klang Valley in Malaysia, which includes the federal territory of Kuala Lumpur, the new administrative city of Putrajaya, and the high-technology center Cyberjaya. Southeast Asian urbanism has its roots in the Chinese-influenced walled-city form, like Bangkok or Mandalay; the Malay or Muslim ports like Malacca, Banten, or Makassar; the court cities like Yogyakarta; and the colonial cities like Yangoon Singapore, or Manila (Evers and Korff, 2000). Next to the city centers with their culturally globalized population, we find localities of migrant groups, still maintaining a sociocultural flavor of their own. The various China towns, 'Little India' in Singapore (Siddique and Shotam, 1982), and localities in greater Manila (Berner, 1997) should not be seen as remnants of traditional culture, but as newly constructed forms of urban society.

Values and Knowledge

Southeast Asian cultures as systems of beliefs, values, symbols, and presentations are as diverse as the ethnic plurality of the local and migrant populations. There are, however, some underlying trends that have been used to construct national cultures or an ASEAN identity. The family and its values, reaching decisions through consensus rather than the majority vote, and a religiously grounded work ethic have been stressed in the debate on Asian values. Social scientists have taken up the cultural analysis of modernity. In his study of Thai, Indonesian, and Philippine middle-class culture, Mulder (1992) has stressed the reinterpretation of classical concepts for the construction of modernity.

The knowledge on Southeast Asian societies is increasing fast (King, 2008). Most of the relevant books and articles are still produced by foreign scholars, affiliated to universities or research institutions around the globe, but an increasing proportion of works is written by Southeast Asian nationals or by scholars attached to Southeast Asian universities (Shamsul, 2011; Evers and Gerke, 2012). An epistemic culture of local Southeast Asianists is emerging, contributing to the further construction of Southeast Asia as a sociocultural unit.

An increasing number of Southeast Asian scientists and knowledge workers contribute to the emergence of knowledge-based economies and societies (Menkhoff et al., 2011), with Singapore and Malaysia as the most advanced countries. Despite the cosmopolitan nature of these societies, ethnic differences still play an important role in politics and social relations.

Southern Africa: Sociocultural Aspects

Abstract

The southern African region comprises of South Africa, Lesotho, Swaziland, Botswana, Namibia, Angola, Mozambique, Malawi, Zimbabwe, and Zambia. The southern African region shares similar and interrelated colonial histories, postcolonial interactions, and the broad outlines of their cultural histories. The Southern African Development Community provides a forum for governmental consultation, and economic and cultural cooperation, but also includes Tanzania, and French-speaking Democratic Republic of Congo, and the Indian Ocean island states of Seychelles, Mauritius, and Madagascar. From the middle of the twentieth century the decolonization process and its aftermath dominated the history of the region, but all countries derive a great deal of their cultural traditions today from the colonial period, including their official, dominant languages, and religion.

The precolonial African cultural heritage is seen mainly in the rural areas, especially in the institutions of chiefship ('traditional authority') that continues to hold a variable degree of autonomy from the state, especially with respect to land rights and land tenure. Swaziland, for instance, remains an absolute monarchy. Mozambique formerly banned chiefship, while tolerating it in practice. Indigenous traditions persist in indigenous healing traditions, divination, funerary, and kinship rituals, and also in many indigenous, nominally Christian religious practices. The former Portuguese colonies, Angola and Mozambique, continue to use Portuguese as their official languages, while the former British colonies and dominions (South Africa) use English. All also have many indigenous languages, with no single African language dominant in any country or across the region. Since the nineteenth century, all countries have had Christian majorities divided into many hundreds of sects and denominations, many with roots in indigenous religious beliefs and practices. Pentecostal and Evangelical congregations are growing rapidly. Small Muslim and Hindu minorities, predominantly of Indian origin, exist mainly along the Indian Ocean coast in South African and Mozambique. South Africa has a significant Jewish population whose ancestors arrived in the nineteenth century, mainly from the Baltic States. Ethnic groups, languages, religious affiliations, and precolonial polities span national boundaries, and movement of populations across all boundaries is relatively uncontrolled.

With a few exceptions, countries have struggled to establish viable democratic political systems and bureaucracies, to overcome ethnic, racial, regional, and economic conflicts, and to diversify and stabilize economies often dominated by only one or two industries (such as mining in Zambia and Botswana, or tobacco in Zimbabwe). Accordingly, overall economic development is precarious, with large informal, untaxed, cash-only economies providing a large proportion of economic activity in all. Botswana and South Africa have the highest per capita incomes, comparable with Brazil, Thailand, or Turkey. Mozambique, Malawi, and Zimbabwe are the poorest, comparable only with other poor African countries such as the Democratic Republic of the Congo. HIV adult prevalence rates (percentage of people infected with HIV in the age range of 15–49 years) are the highest in the world, ranging between roughly 10% in Malawi and 27% in Lesotho, Botswana, and parts of South Africa. Largely because of extremely high HIV/AIDS prevalence, malaria, and TB, life expectancy ranges between 48 and 58 years compared with a world average life expectancy of 70 years.

The small countries of Lesotho, Botswana, and Swaziland are, for the most part, monoethnic states dependent on South Africa, but have significantly different internal political arrangements and economic fortunes. South Africa is the most economically and ethnically diverse country in the region, with the strongest state and institutions of civil society. It dominates the region's economy. All other countries, especially landlocked Lesotho, Swaziland, Zimbabwe, Zambia, and Malawi, depend to a large degree on South African transport services and harbors. South African investments and companies increasingly dominate the economies of its regional neighbors.

Regional trade volumes increase annually, but the largest trading partners still remain outside of the region, primarily in Western Europe, but increasingly in China and India. At the beginning of the twenty-first century, all countries had begun to seek increasing intraregional cooperation in order to reverse the effects of conflict, isolation, economic decline, and political weakness of state structures. Thabo Mbeki, President of South Africa from 1999 to 2008, articulated this as the search for an 'African Renaissance,' but the concept proved to have little resonance by the early twenty-first century, even as regional economies, cultures, and populations continued to converge.

These factors both constrain and help to shape the sociocultural aspects of the region.

History

Paleoanthropological and archaeological evidence shows that 'the cradle of mankind' included southern Africa, and extended north to Ethiopia and Somalia. The earliest prehumans and humans evolved in the region, but then moved north out of Africa, apparently disappearing entirely from southern Africa between 70 000 and 40 000 years ago. Although these early humans were the ancestors of all of humanity, there is no evidence that links them directly to contemporary southern African populations. Earliest ancestors of the San (Bushman)

and Khoe (also Khoikhoi, Khwe, Hottentot) appeared in the archaeological record again around 20 000 years ago, while ancestors of the dark-skinned people from Central Africa began to appear around 2000 years ago. People from Europe first settled in South Africa 500 years ago, and in Angola, Namibia, and Mozambique shortly after that. Trade with the Indian Ocean existed along the coast of Mozambique up to 2000 years ago, and with the interior perhaps 1000 years ago. Small populations of Indians arrived in South Africa and elsewhere in the region from the mid-nineteenth century. Even smaller population of Chinese arrived around the same time, but south Asian and Chinese populations in all countries began to increase rapidly in the early twenty-first century. Today, all towns and cities in South Africa, for instance, have significant recently arrived Chinese, Indian, and Pakistani populations.

All African languages in the region derive from only two of the six major language families of Africa (Greenberg, 1966; Heine and Nurse, 2000, 2011), but most named languages are in fact clusters of dialects. The speakers of the diverse Khoisan language group (comprising five clusters, that are at best distantly related to each other) have lived in the region, and only here, from at least 20 000 years ago. These languages, noted for their click sounds that occur nowhere else in the world, are all but extinct today. Beginning around 2000 years ago, people speaking languages of the Bantu family, and possibly also the Khoe speakers, moved into the region quite rapidly from the north. Bantu languages originated north of the Congo forest zone in the region of today's Cameroun, while the Khoe languages may have come from the northeast. At about the same time, technology to smelt iron and make durable fired pottery spread throughout the region. Cattle, goats, and a mixture of crops from the Sudanic zone (millets and sorghum) and from the Indian Ocean region (sweet potatoes, bananas) also began to appear. At some time a crop from the New World, maize, became central to the diet of the entire region well before European incursions.

Before the arrival of agriculture, sheep, goats, and cattle, and just before the first millennium CE, the Khoisan people sparsely populated most of southern Africa. The Khoisan language family includes the Bushman (San) languages and the KhoeKhoe (also Khoi, Kwe, Hottentot). Social and economic difference distinguished the two groupings. The Bushman were primarily hunters and gatherers, living in small mobile bands of no more than 35–40 people. The Khoe were cattle and sheepherders, living in larger tribal groupings. Early European settlers at the Cape of Good Hope began to trade with the Khoe peoples (then known as 'Hottentots') in the seventeenth century, but as trade relationships broke down and as European pastoralists and farmers ('Boers') began to move inland in the eighteenth century, most Khoe pastoralists were gradually absorbed as clients and laborers, and occasionally as wives, by the Boers. Bushman were killed in skirmishes, displaced to remote deserts, or incorporated as servants and wives by European people moving inland from the south, and by Bantu-speaking Africans moving southward. By the nineteenth century, Khoisan speakers remained only in the dry areas inland from the west coast of South Africa, Namibia, and Angola, and in the Kgalagadi (Kalahari) desert of Botswana. The relatively large Nama (Khoi)-speaking group in Namibia (11% of only 2 million people) give 'Namibia' its name ('land of the Nama'). In South Africa where 'colored' people preserve much of the San and Khoe genetic heritage, Bantu languages such as Xhosa and Zulu preserve the linguistic heritage in the form of some vocabulary borrowed from the Khoisan speakers, and the characteristic 'click' sounds that were adopted by the Nguni languages (Zulu, Xhosa, Swazi). Their art, painted on rocks throughout the region, gives testament of a rich culture.

People who speak languages of the Bantu languages family also share broadly similar cultures. With the exception of their spread to Indian Ocean islands such as the Comoros and Zanzibar, they are restricted to tropical and subtropical continental southern, central, and eastern Africa. The culture and political economy of early Bantu speakers, like the Khoe, were characterized by residence in small, dispersed agricultural and pastoral settlements. A leading man or 'chief' usually presided over a 'court' composed of senior or royal males. The court usually excluded women, but included all surrounding people who wished to acknowledge the court's authority. In the precolonial period most people moved in small groups, combining and splitting from one another over time. Settled polities began to emerge in the fifteenth to sixteenth centuries, as, for example, around the court known as Great Zimbabwe and a few other large towns, sacred sites, and senior courts. Loose alliances and trade networks were formed between settlements, kin groups, and courts throughout the region. As these people were gradually incorporated into colonial states, formal hierarchies of chiefs developed, and became incorporated into a hybrid political system. Missionaries named languages for the purpose of translating the bible, and to enable governments to establish schools, only in the nineteenth century. Political boundaries and ethnic identities as they exist today did not emerge until the late eighteenth century.

Precolonial ritual practices focused on communication with the ancestors, healing cults, and acts intended to bring rain, fertility, and protection from witches, evil, and disease. Individuals, families, clans, or larger tribal or village groupings conducted rituals regularly. While there were generally no 'priests' in these traditional ritual systems, all societies relied on diviners, healers, and prophets who acted either as mediums for spirits during healing rituals or occasionally interpreted the will of the spirits in a political context. Specialist healers, 'shamans,' spirit mediums, or *sangomas* achieved altered states of consciousness known as 'trance' during these occasions. The institution of religious prophecy continues to have significant political and social effects. The role of traditional prophets and spirit mediums in the *Chimurenga*, 'war of liberation,' fought in Rhodesia-Zimbabwe was especially important, but resistance and syncretic religious movements led by traditional prophets appeared in all southern African countries during colonial times, and are still important. Strong beliefs in the existence of witches – individuals who caused evil or illness often unbeknownst to themselves – and beliefs in the existence of animal familiars of witches or other kinds of spiritual powers inherent in plants and animals are also widespread. Today, majorities in all countries are at least nominally Christian, with small numbers of Muslims such as the Yao of Mozambique, and the Swahili speakers in Mozambique, Malawi, and eastern Zambia. Many aspects of

precolonial belief have been incorporated into indigenous Christian beliefs and practices, while minorities of people continue to practice traditional religion in preference to, and sometimes in combination with, Christianity or Islam.

The warrior king Shaka established the Zulu kingdom in 1816 as the culmination of a series of raids and wars that gradually incorporated large numbers of agricultural and pastoral peoples in the southeastern lowlands ('lowveld') of South Africa. Repercussions of the Zulu conquest were felt as far north as Malawi and eastern Zambia, southern Tanzania and Mozambique, where displaced groups of people under warrior chiefs established temporary hegemony. These people were known as the 'Ngoni' in the north, or Nguni and Ndebele (Matebele, 'people of the court') in the south. Shaka is credited with introducing a number of military innovations, and with the banning of circumcision rituals, a social innovation that allowed him to recruit males into armies under his command. They met the British colonial advance in the latter half of the nineteenth century. The battle between Zulu and British armies at Isandlwana in 1879 was a famous defeat for the British forces, but the Zulu were eventually overcome and incorporated into the Colony of Natal. The contemporary name of the South African province of KwaZulu-Natal province recognizes the continuing balance between 'Zulu' and English and Afrikaans languages and cultures today.

The rise of the Zulu kingdom, together with movements inland of the Portuguese from the east coast, and the Afrikaners (Boers) from the British colony of Cape of Good Hope, led to general disruption of settled life in south-central Africa. This, in turn, created opportunities for widespread incursions, first by African and Arab slave and ivory traders from the east coast, and later for European adventurers, hunters, traders, settlers, and missionaries. The general lack of strong centralized states or other large-scale political organizations in the region contributed to the advance of colonial rule and expropriation of land by Europeans for farms and mines.

European Christian missionaries established mission stations in Nyasaland (now Malawi) in response to the devastation and social dislocation caused by Ngoni/Nguni incursions and led the way for the British government to declare Nyasaland a Protectorate. Zulu offshoots established the Gaza kingdom in the southern central region of Portuguese Mozambique over the Tsonga-speaking people and settled in large numbers in southern Zimbabwe as the 'Ndebele' people. Tswana-speaking groups, originally deriving from ancestral peoples known in the nineteenth century as 'Hurutshe' (also Ro(t)ze, Rozvi, Rotse) in the central highlands region of South Africa, Botswana, and Zimbabwe fled north in response to Zulu incursions and established temporary hegemony over the Lozi/Rotsi people in western Zambia, known as Barotseland. They managed to impose much of their language and culture on the previously independent populations. In South Africa, the Zulu expansion and its repercussions had the effect of disrupting virtually all previous settlements of people during the *Mfecane* (also *Difeqane* in Sotho, 'the crushing'), a period of vast population movements and reorganization lasting through the middle of the nineteenth century. Out of this emerged several strongly integrated 'tribes' as followers of powerful chiefs: the Sotho of Basutoland (now Lesotho), the Swazi of Swaziland, and the Tswana tribes of Bechuanaland (now Botswana). It also created an opportunity for white Afrikaans-speaking farmers, the Boers, to move north out of the Cape Province, a British Colony since 1802. After the Great Trek of 1836–37 during which hundreds of Afrikaans farmers moved north out of the Cape Colony, they established several independent republics, including the Orange Free State and the Suid-Afrikaanse Republiek ('South African Republic,' known as 'The Transvaal'). These maintained independence until British colonial forces defeated them during the South African War (1899–1902), also known as the 'Boer War,' or the 'Second War of Independence' by the Afrikaans-speaking citizens of these republics. Some of the earliest instances of 'guerrilla warfare' (informal, hit-and-run) occurred after the Boer forces were defeated in conventional battles. The first 'concentration camps' were created in which many Boer families were interned and died. Resentment and political tension between the Afrikaans-speaking (Afrikaners) and the English-speaking white South Africans continued to define political events for most of the twentieth century, while tension between black and white South Africans in the same period eventually led to the fall of Apartheid and constitutional, universal-franchise democracy from 1994.

Colonialism and Independence Struggle

In the late nineteenth century, Swaziland, Basutoland (now Lesotho), and Bechuanaland (Botswana) were declared British Protectorates after the chiefs or kings of these semi-independent polities signed treaties. This was done partly in order to secure them as labor reserves to provide labor for European farmers and the mines, and partly to keep them from the hegemony of the Zulu on the one hand and the Afrikaner (Boer) states on the other. The Zulu, unwilling to enter into negotiations, were eventually defeated in 1879 by British forces. Their king was exiled briefly but eventually returned as king of the Zulu people under the authority of the Colony of Natal.

Mozambique was colonized by Portugal in the fifteenth century but only came under effective control in the late nineteenth century. Zambia and Zimbabwe (previously Northern and Southern Rhodesia) were given as concessions to the British South Africa Company under Cecil John Rhodes, becoming known as Rhodesia in 1895. In 1924, the British South Africa Company was dissolved, and Northern Rhodesia and Southern Rhodesia became Crown Colonies under local white settler control. Together with the Protectorate of Nyasaland, they joined together in the Central African Federation in 1951 until independence was achieved by Northern Rhodesia and Nyasaland in 1964. The colony of Northern Rhodesia was renamed Zambia, while Nyasaland became Malawi.

Military conflicts in the later decades of the twentieth century severely limited the pace of economic and political development throughout the region. Protracted guerrilla struggles between settler populations (European with some from India) and black African nationalist organizations in Mozambique, Zimbabwe (former Southern Rhodesia), Angola, and Namibia (former South-West Africa) spanned most of the last half of the twentieth century. These conflicts generated

large cross-border refugee movements that, together with labor migration and urbanization, have resulted in large and long-term shifts in populations of all countries. Urban growth has been greatest in South Africa and Angola, and least in Malawi and Lesotho.

Southern Rhodesia continued to be ruled by its white minority 'settler' population as Rhodesia, and declared its independence from Britain in 1965. Though unconstitutional and condemned by Britain and the United Nations, the largely white government under Prime Minister Ian Smith continued to rule Rhodesia until 1980, despite massive trade and political sanctions. After the Zimbabwe African National Union (ZANU), with an ethnic base among the Shona, and the largely Ndebele Zimbabwe African Peoples Union (ZAPU) succeeded in defeating the white settler regime, Rhodesia became Zimbabwe under Robert Mugabe, the leader of ZANU. The defeat of the Smith's Rhodesian government was made possible by close cooperation between ZANU and African nationalist forces in Mozambique. These had begun by the late 1960s to wage a war of liberation, and offered safe havens for ZANU forces.

Zimbabwe's independence was followed by a period of violent repression by ZANU against the Ndebele followers of ZAPU from the middle of the 1980s, though peace was eventually restored. Mugabe's rule became increasingly autocratic despite maintenance of some democratic features, including elections. Twenty years after independence, Mugabe's government expropriated much of the land that was under the control of the country's remaining farmers of European descent. This group still retained about half of the arable land, and many of these farms were transferred to politically connected members of Mugabe's inner circle, while other farms were occupied by subsistence farmers, or were neglected and returned to bush. At the turn of the millennium, Zimbabwe entered a period of economic and political collapse. Its currency inflated to bizarre levels, and was eventually abandoned in favor of the US dollar and the South African Rand.

Operating from Tanzania, the Mozambique Liberation Front (FRELIMO) succeeded in gaining control of northern Mozambique in the early 1970s. In 1974, the Portuguese colonial government fell, due in large measure to the cost of its colonial wars in Angola and Mozambique. Mozambique was granted independence in the following year but suffered 16 years of civil war between FRELIMO and the Mozambique National Resistance (RENAMO) after the Portuguese withdrawal. Namibia, the former South-West Africa, had been brought under German control as a result of the Partition of Africa at the Berlin Conference in 1884. It was seized by South African forces acting under British authority during World War I, and then ceded to South Africa as a Trust Territory under the terms of the Armistice, and in accordance with a mandate of the League of Nations. After a protracted liberation struggle, it became independent Namibia under the government of its liberation organization, the South West People's Organization. German and Afrikaans are still widely spoken in Namibia, although English is the official language, and the Ovambo constitute about half the population.

With its Portuguese colonial heritage, Mozambique is clearly part of the southern African region culturally and historically. The Tsonga-speaking people of southern Mozambique straddle the border with South Africa. Mozambicans have long been intensively involved in the South African economy, first as labor migrants to white farms from as early as the eighteenth century, and later as laborers on South African mines from the late nineteenth century until the present. South African capital has flowed strongly into Mozambique after the end of its protracted civil war.

In South Africa, the African National Congress (ANC) came to power in South Africa in 1994 after the release in 1990 of Nelson Mandela from 24 years of imprisonment. With the end of colonialism, in all countries except South Africa, large numbers of white people withdrew, either moving back to European countries, or Israel, or into South Africa. Today, well over 95% of the population of all countries except South Africa is black African although economically significant minorities of European, Indian, and 'mixed' descent also live in all countries.

States and Politics

With the exception of South Africa, state institutions in the region are all relatively weak. The colonial states of Mozambique and North and South Rhodesia were never very strong, focusing mainly on controlling black labor migrations and political movements, and on delivering security and services to white farmers, miners, and business interests. Partly autonomous chiefdoms in rural areas and the activity of liberation forces also removed large areas from effective government control. Parts of these countries remained effectively beyond the reach of the state, neither paying much in taxes nor receiving many services from the central authorities. At the end of the twentieth century, however, all except Swaziland had democratic governments elected under universal franchise. The benefits of the postcolonial transition to democratic politics have been limited, however, by long liberation struggles in some cases (Zimbabwe, Mozambique, Namibia), postcolonial civil war (Mozambique), rampant corruption, mismanagement (Zambia, Zimbabwe, Malawi), and, for most, increasing poverty and environmental damage.

Throughout the last half of the twentieth century and the early twenty-first century relatively few persons and parties dominated the political process. Twenty years after the first universal-suffrage elections in 1994, however, South Africa had very active civil society, with three presidents having been elected. There were 142 registered political parties, most of them small, with only 13 represented in the national parliament. The ANC dominated national power centers, while the Democratic Alliance governed one province. Zimbabwe's two parties, the Movement for Democratic Change and Zimbabwe African National Union–Patriotic Front governed by coalition from 2009 to 2013, but then reverted to one party rule under Robert Mugabe, president since 1980. All other countries have been ruled for long periods by one party and by a few long-term presidents. Free political expression has often been suppressed. In South Africa, the National Party, dominated by white Afrikaners, ruled from 1949 until 1994, one of the longest periods of rule by a single party anywhere in the postwar world. The National Party implemented a set of laws and practices known as Apartheid ('separateness') that attempted to maintain exclusive political and economic power by 'whites,'

that is, people primarily of European descent who spoke Afrikaans and English. Racism was institutionalized, and black opposition parties were banned. Their members, such as the ANC leader Nelson Mandela, were either jailed or forced into exile. Only whites were allowed to vote. Within these limits, however, the political process was orderly, with presidents stepping down after their terms of office had expired. Following this trend, Nelson Mandela, the first president of a free South Africa, stepped down after serving a 5-year term to make way for Thabo Mbeki, his elected successor, who was succeeded in turn by Jacob Zuma.

The problem of how to integrate 'traditional' African politics of the rural areas (based on territorial, tribal, and kin-based polities) with the modern, urban-centered political systems deriving from Europe (either liberal-democratic or centralist-Marxist) has persisted to the present. While Botswana, Lesotho, South Africa, and Zimbabwe maintained 'advisory' constitutional roles for 'traditional authorities' (that is, predominantly rural tribal 'chiefs'), others such as Mozambique formally abolished chiefship. Tribal groups such as the Himba in Namibia and the Lozi of Zambia maintain kings, but without recognition by the state's constitution. With the exception of Swaziland, all possessed more or less liberal-democratic parliamentary political systems by the end of the twentieth century. Swaziland's absolute monarchy is based partly on precolonial African traditions of governance and partly on modern bureaucracy and police power. Botswana institutionalized traditional rulers who have a role in government through the House of Traditional Authorities. Lesotho maintained a constitutional monarch in an otherwise democratic dispensation. In white-ruled Zimbabwe (before 1980) and South Africa (before 1992), rural chiefs became an integral element of government control and were subsequently seen as part of Apartheid's oppression. During the 1970–80s, the Apartheid government created internal 'homeland republics' under the institution of modernized, salaried chiefships provided with minor bureaucratic support. Surprisingly, the twenty-first century saw strong continuity of these institutions in South Africa, even as intense political conflict grew around the role and power of local chief's courts in the national judicial system. In Mozambique, remnants of precolonial traditional political systems tended to divide the country into a traditional north, represented by RENAMO, and a more modernizing south, represented by FRELIMO, resulting in protracted civil war from 1977 to 1992. Chiefs continue play public roles in countries of the region.

Livelihood

While South Africa began to develop industrial-scale mining and large industry from the late nineteenth century, all countries have small industrial sectors today. Angola possesses huge oil reserves, while Zambia's copper mines have been central to its economy. In the later decades of the twentieth century, all countries in the region suffered periods of isolation from world markets as the result of political sanctions (Rhodesia-Zimbabwe and South Africa), distance from markets (Lesotho, Malawi, Zambia, Swaziland), warfare (Mozambique, Angola), or declining market prices for their primary products (Zambia). Worldwide political and economic sanctions were applied first to Rhodesia (Zimbabwe) throughout the 1970s during the period of white settler rule, and then to South Africa during the final decades of the struggle against Apartheid.

A polarity between the 'modern' urban centers and the surrounding 'traditional' rural regions has characterized the broad politico-economic structure of the region since colonial times. Throughout the twentieth century migration of rural, mainly agricultural people to urban areas has skewed gender balances as males moved to urban areas in search of wage labor, especially in mines and industry, while women tended to stay in the rural areas. Over two-thirds of the South African population is urban, while only one-third of Mozambique's population is urban, with other countries falling into this range. By the beginning of the twenty-first century, over 95% of whites and Indians in South Africa were living in urban areas but Black South Africans were less urbanized at 62% over all. Damage to family structures, unemployment, urban crowding, severely limited police capacity, and poor urban planning have often led to high levels of social insecurity and criminal violence throughout the region. Rural–urban migration and gender balance had stabilized by the end of the millennium, but high levels of mobility between city and country remained, with families and kin groups often attempting to maintain bases in both.

In Zambia, urbanization proceeded rapidly during the colonial period, with miners and work seekers clustering in the 'Copper belt' in the north-central Zambia. With collapsing copper prices during the 1980s and mismanagement of mines, many people returned to rural areas. Rural subsistence agricultural areas are characterized by dispersed residence, small-scale agriculture, and pastoralism, usually producing no significant economic surplus for trade.

Urban areas throughout the region are weakly centralized and sprawling. All large urban areas derive from colonial patterns of segregated 'suburbs' loosely grouped around multiple trading and industrial centers. Single houses (or complexes of houses, outbuildings, and shacks) surrounded by walled 'gardens' or yards comprise the formal urban settlement pattern in all of the countries' urban areas, while large informal shack settlements surround them.

The colonial economy based on mining, large-scale estate farming, and labor migration contributed to disruption of family life and systems of social control, especially in rural areas of Zambia, Zimbabwe, and South Africa. While mining and agriculture now account for less than 10% of the GDP in South Africa, these two sectors dominate the economies of other southern African countries as they did in South Africa in the early twentieth century. Lesotho and Malawi, lacking natural resources except water, have been largely labor-exporting countries, relying on remittances sent home by miners who work mainly in South Africa, but also in Zambia and Zimbabwe. The bulk of Botswana's GDP is derived from diamond mines, while Zambia relies on exports of copper, cobalt, and other minerals. Namibia is mostly arid, and depends on mineral exports, especially uranium, for foreign exchange earnings. All countries, however, participate in sending labor to the mines located throughout the region but dominated by South African mining houses.

At the beginning of the twenty-first century, economic and social prospects are dimmed by the HIV/AIDS pandemic. Southern Africa emerged as the hardest hit region in the world. The rate of population growth is predicted to fall below replacement rates in the first decade of the twenty-first century.

Language and Communication

The process of urbanization has resulted in the emergence of distinctive urban cultures with small manufacturing, trade, mining, and transport industries initially attracting large numbers of formerly rural people to urban areas, where different languages and cultures came into contact. They blended to form new urban-based languages and cultures. Examples include Isicamtu, 'talking' or tsotsitaal, 'gangster language,' in South Africa, based on Zulu grammar but blending English, Afrikaans, and Sotho or Twana words; or Fanagalo, meaning 'Do-like-this,' a pidgin based on Zulu used on the mines and farms throughout southern Africa. With the exception of the isolated Khoisan languages, all languages in the region, including English and Afrikaans, frequently grade into each other and borrow vocabulary and new linguistic forms from each other. New forms of music, dance, and religion blending African traditions and Western forms also arose.

No indigenous African language has achieved status or acceptance as a single national language or lingua franca anywhere in southern Africa. South Africa has 11 official languages, of which those with the largest number of first-language speakers are Zulu, Xhosa, Afrikaans, Pedi ('Northern Sotho'), and English, followed by, Sotho ('Southern Sotho') and Tswana (often 'Sotho-Tswana'), with smaller linguistic communities of Tsonga ('Shangaan'), Venda, Ndebele, and Swati ('Swazi'). Other languages spoken include Gujarati, Urdu, Hindi, Tamil, and Bhojpuri from India. Portuguese, Greek, and German are spoken by smaller communities from Europe. Chinese is spoken by recent immigrants from China and Taiwan, although the small community of Chinese who arrived in the nineteenth century speak only English. French is spoken primarily by Central African refugees and migrants in South Africa.

The linguistic diversity is even greater in Zambia, where 41 languages are spoken, including Bemba, Tonga, Nyanja (Chewa), and Lozi. In Mozambique, 33 languages are spoken, including Makuwa (Makua) in the north and Tsonga in the south. In Namibia 28 languages are recognized. Although over 70% of the population of Botswana speak Tswana, there are many small, nearly extinct languages spoken by Khoisan people, and by refugees from surrounding countries.

There is some mutual intelligibility among some of these languages. For instance, Sotho-Tswana languages (Pedi, the Sotho language of Lesotho, and Tswana) form a set of dialects, and the 'Nguni' languages (Zulu, Xhosa and Swazi) are similar and mostly interintelligible. Several languages have become lingua francas within limited areas of these countries – for instance Zulu in South Africa, or Bemba and Nyanja/Chewa in Zambia and Malawi. Almost all people speak several regional languages. As a consequence of this diversity, English has increasingly become the public language of government and the media even in the Portuguese-speaking countries. It is also the language of trade and diplomacy.

While Mozambicans use Portuguese as the language of government and education, they are increasingly turning to English, too, as they develop deeper political and economic links with other nations. Nevertheless, the large majority of all people in the region continue to rely on local Bantu languages at home. Afrikaans is indigenous to South Africa, where it evolved from dialects of Dutch in the Dutch colonial settlements at the Cape of Good Hope in South Africa. Today it is spoken throughout South Africa and Namibia, with small pockets in other southern African countries.

Within the region, South African society is the most complex with respect to color, race, religion, language, dialect, region, and class. Ethnic, political, and other kinds of identities – such as preference for certain sports or foods – are based on these differences, and also help to create and sustain them. After independence in Angola and Mozambique, many whites either went to Portugal or migrated to South Africa. Similarly, large white and Indian populations in Zimbabwe and Zambia also moved to South Africa, or left the region. These migrations greatly reduced ethnic and racial diversity in all of these countries.

Despite the previously enforced divisions and centuries of conflict across many different cultures and language groups, South Africa exhibits a degree of cultural, economic, and political unity that is perhaps unique in Africa. Virtually all of its people manage to communicate with one another in one or several common languages, shop in the same stores, watch the same television channels, furnish their houses in similar ways, and – ironically – share the belief that they are much more different from one another than they actually are in terms of many objective measures of cultural or social difference.

None of these primary indicators of social difference, however, tend to define a consistent or bounded category of people. In other words, people of many different colors or race speak the same language or set of languages, while people of the same region or class vary widely in what religion they follow, or in their political allegiances. People sharing the same religion and language – which is often a combination that defines a fairly closely knit ethnic or national community in Europe or Asia – may span widely different colors, classes, and regions in southern Africa. For instance, the majority of South Africa's 'colored' people speak Afrikaans and belong, like most white Afrikaners, to some denomination of the Reformed Church. Surprisingly, while virtually all schools and public places were rigidly divided by Apartheid policies in South Africa, by the early twenty-first century, schools, shopping centers, and other public places had quietly integrated with no more than a handful of violent or other racial incidents. Urban areas in all countries are marked by wealthy enclaves, often separated by walls and advanced security systems that are often surrounded by much poorer 'suburbs' and large shack and informal settlements of the very poor.

http://www.aluka.org – Aluka, African Cultural Heritage Sites and Landscapes Collection, part of JSTOR (www.jstor.org, a non-profit shared digital library), is an archive of visual, contextual, and spatial documentation of African heritage sites, including southern African countries, especially South Africa and Mozambique including the 'Arquivo Histórico de Moçambique.'

Space and Social Theory in Geography

Barney Warf, University of Kansas, Lawrence, KS, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Social theory and the analysis of spatiality have a long and rich history. Building on earlier traditions such as Marxism, feminism, and humanistic geography, this article addresses the major lines of conceptual thought in human geography in the early twenty-first century. It encompasses the discipline's major theoretical constructs under the broad umbrella of social constructivism and political economy, largely based on the work of Foucault. These precepts serve as a guide to the role and impacts of various forms of social theory in the analysis of multiple topics, including cultural geography, critical political geography, economic geography, the geographies of cyberspace, critical cartography, and GIS, and the social construction of nature.

Over the last four decades, contemporary human geography has embraced social theory with a vengeance. Building on several earlier schools of thought that emerged in the wake of positivism, including various forms of Marxism, feminism, structuration theory, and postmodernism, the intellectual landscape of human geography in the twenty-first century resembles a palimpsest consisting of multiple, overlapping, and intersecting layers. There is, to be sure, enormous variation among and within each of these lines of inquiry, as well as many apt summaries (e.g., Gregory, 1994; Benko and Strohmayer, 1997; Peet, 1998; Warf, 2004). Many, for example, draw on the enormously influential works of Michel Foucault (Crampton and Elden, 2007), which decisively sutured together power, knowledge, and space.

Given the diversity of theoretical views within the discipline today, it would be foolish to impose an artificial homogeneity that claims to represent all such perspectives. However, if any theme may be said to run throughout the diverse perspectives that characterize the field, it is social constructivism. Many entities once taken as given – as somehow lacking in social origins and consequences – have been revealed as the products of social relations embedded in particular times and spaces. The body, gender, ethnicity, poverty, even nature itself, all have been revealed as the contingent, power-laden products of configurations of class, power, discourse, and other dimensions of social life. Social constructivism points to the origins of phenomena within circuits of power and knowledge, the interests that are served (or not) by particular discourses, their effects and consequences, and the contingent ways in which they unfold under different historical and geographical circumstances. Constructivist perspectives have played out in different ways in various domains of human geography, including the cultural turn in economic geography, the poststructuralist emphasis on networks, critical geopolitics, critical cartography and participatory GIS, political ecology and the social construction of nature, and the growing interest in hybridity. One result of geography's intellectual sophistication is that a field long characterized by insecurity about its position within the academic division of labor has won newfound respect. Indeed, across a remarkably diverse range of disciplines, ranging from the humanities to the natural sciences, space, place, and spatiality have decisively inserted themselves into contemporary forms of knowledge production, a phenomenon that has come to be widely seen as the spatial turn (Warf and Arias, 2008).

Much of human geography has been deeply affected by poststructuralism (Harrison, 2006; Murdoch, 2006), a loosely related array of perspectives that reflect social constructivism's intersections with critical philosophy and literary analysis. Like an earlier generation of postmodernists, poststructuralism emphasizes the plurality of social worlds in which people live, an abiding concern for otherness and difference (and the power relations that shape it), and a deep empathy for the socially and politically marginalized. It recast once-given universal categories (e.g., 'women,' 'African-Americans') in the plural, emphasizing the diversity within as well as among groups. In addition to a rejuvenated politics of identity, which informs much of critical political and cultural geography, poststructuralism opened the door for analytical approaches such as actor-network theory (Bosco, 2006; Latour, 2007). Moreover, the rejection of all dualities – nature/society, global/local, black/white, economic/cultural, even human/nonhuman – as artificial and misleading remnants of modernist thought (Cloke and Johnston, 2005) gave rise to an insistent focus on hybridity as the antidote to the essentialisms that such categories create (Whatmore, 1997, 2001; Kwan, 2004). For example, in following Latour and transcending the human/nonhuman dichotomy, animal geographies have become adept at exploring the interface between humans and nonhuman animals (Urbanik, 2012).

In rejecting fixed categories, essentialisms, and dualisms, emphasizing the plural, human geography came to theorize all relations, both social and spatial, in relational terms. Massey's (2005) notion of power geometries played a key role in this process, in which networks became the defining metaphor of geographic interaction. Those drawing on the Deleuze-Guattarian 'flat ontology' have come to reject scale itself as an unnecessary obfuscation (Marston et al., 2005), stimulating a lively debate about the meaning and relevance of scale in a relational world (Paasi, 2004; Jones, 2009; MacKinnon, 2010). The emphasis on geographies as fluid and ever-changing also led to renewed emphasis on movement and mobility (Cresswell, 2006; Larsen et al., 2006), in which place has been conceptually repositioned as a process rather than a thing.

Cultural Geography

Now one of the discipline's most theoretically sophisticated fields, cultural geography, exhibits numerous lines of theoretical inquiry that address the role of culture at multiple spatial scales, ranging from the social construction of the body to geographies of sexuality and ethnicity to the lasting impacts of the colonial imaginary.

Bodies, once taken for granted as given and now firmly embedded in their cultural milieu, have become instrumental to works on the spatiality of emotions and affect (Thrift, 2004, 2008; Thien, 2005; Tolia-Kelly, 2006; Lorimer, 2008; Anderson and Harrison, 2010). Nonrepresentational theory, which has been highly contested, merges long-standing interest in geographies as embodied social processes with poststructuralist interrogations of language to portray human beings as more than discursive products but also as deeply shaped by forces that have long been marginalized by the Enlightenment obsession with rationality, as manifested in the long-standing reign of the Cartesian cogito. Emotions, for example, once dismissed as atavistic or insignificant, have assumed pride of place in contemporary theorizations of the subject and subjectivity (Pile, 2010). Likewise, following Judith Butler, social roles once assumed to exist externally to the individual and acquired through socialization are now largely viewed through the lens of performativity (Nash, 2000).

Human geography's embodiment of social and spatial relations has deepened its engagement with sexuality (Howell, 2007). Drawing heavily on Foucault, this focus has centered largely on sexual minorities, including the construction of queer spaces at multiple spatial scales ranging from the body to the gay rights movement to global patterns of discrimination (Brown and Knopp, 2003; Oswin, 2008). Other variants have delved into the spatiality of masculinities (Berg and Longhurst, 2003), largely displacing earlier notions of gender that equated it solely with women and femininity, as well as sex workers and the intersections of sexuality, class, gender, ethnicity, and location.

Similarly, ethnicity, which has decisively displaced older notions of 'race,' has acquired new attention (Phillips, 2007). By contextualizing race as an ideology – as a socially constructed relationship, not a biologically determined 'given,' this literature has illustrated the complex ways in which race is constructed, experienced, and negotiated in everyday existence, how it intersects with class and gender, and the manner in which racial relationships of domination and subordination play out over space and time. Like gender, ethnic identity is fundamentally a power relationship that typically reflects, reinforces, and naturalizes existing lines of inequality, although it may also challenge hegemonic norm relationship. Race may be illusory in that it is socially created, but, as Peake and Schein note (2000), its effects are nonetheless quite 'real': denaturalizing race thus unmasks the power relationships that construct it socially and discursively. Because racial and ethnic identities are important in social reproduction, individual and collective identity, and the allocation of resources over space and time, race and racism are simultaneously material and discursive processes that reflect and constitute social relationships and places. The geography of whiteness reveals that it too is socially constructed in ways that render it invisible, as the 'default option' against which 'ethnic' identities are assessed (Dwyer and Jones, 2000). The 'naturalness' of whiteness – the assumption that it is not an ethnicity, hence not constructed, a position that equates ethnicity with nonwhites – is a large part of the power of institutionalized racism. Pulido (2000) points out that white privilege takes many forms and that its existence is typically rendered invisible. Racism can be intentional or unintentional, although, as she notes, "by reducing racism to a hostile, discriminatory act, many researchers…miss the role of structural and hegemonic forms of racism in contributing to such inequalities" (2000, 12).

Cultural geography's examination of colonialism, both past and present, as a discursive and ideological force has had significant implications for the analysis of globalization, including the role of indigenous peoples (Nash, 2002; Clayton, 2003; Sharp, 2009). Inspired by Edward Said (1978), postcolonialism in many respects represents a fusion of political and cultural geography, one that grapples with the powerful material and discursive effects of Western hegemony. Gregory's (2004) fascination with the Middle East, particularly the injustices visited upon Muslim peoples by Western powers, has been central to this project. Postcolonialism continues to inform efforts to understand differential trajectories of regional development and the goals and strategies that inspire them (Radcliffe, 2005).

Critical Political Geography

Inspired by the critical geopolitics of the 1990s (especially Ó Tuathail, 1996), political geography has undergone a sustained engagement with issues of discourse, culture, and identity, including feminist thought (Hyndman, 2004). Following Foucault, power is conceived largely in terms of its linkages to knowledge and ideology, funneled through numerous channels, simultaneously discursive and material, contingently exercised, and invariably resisted. Its effects are seen throughout the rhythms of daily life and social reproduction, including the media, educational systems, and the geopolitics of the body. Issues of immigration and citizenship loom large in this respect (Staeheli, 2011). As a result, popular culture has also received pride of place in this school, including comics and religious fundamentalism (Dittmer, 2005, 2008, 2012) and the broader phenomenon of banal geopolitics (Leib, 2011).

In the same vein, drawing on the enormously influential work of Edward Said (1978), orientalism has been the topic of repeated inquiries in political geography, including its internal variants (Jansson, 2003; Johnson and Coleman, 2012). Many geographers drew on the work of Giorgio Agamben (2005) and his thesis of the 'state of exception' to examine the geopolitics of the war on terror, including, for example, the Guantanamo prison in Cuba (Gregory, 2006).

Globalization has had important repercussions for political geography, including the continued viability of the nation-state and the rapidly changing significance of borders (Diener and Hagen, 2009; Popescu, 2011). Viewed through the telescope of social constructivism, territory too is a product of political relations (Forsberg, 2003). Finally, as environmental issues have grown in severity across the planet, environmental geopolitics has gained mounting significance (O'Lear, 2010),

including struggles over water and the paramount issue of anthropogenic climate change and its effects (Raleigh and Urdal, 2007).

Economic Geography

Economic geography's embrace of social theory has led to widespread changes in how the spatiality of economic activity has been conceived and theorized. Perhaps most significant has been the erasure of the long-standing dichotomy between 'society' and 'economy,' following the pioneering efforts of Granovetter (1985). An important step in this process was Florida's (2004) celebrated and enormously influential notion of the creative class. In this reading, the skilled professionals so central to cognitive-cultural urban economies place a high value on amenities, recreational opportunities, and local social climates that value diversity, including ethnic differences and tolerance of alternative lifestyles (notably gays). Cities that are tolerant, Florida maintains, are economically healthy; those that are restrictive and xenophobic are unlikely to attract the talent they need to remain competitive. Critics of Florida (e.g., Scott, 2006) argue that the creative class thesis underemphasizes the locational dynamic of urban agglomeration and the intense pressure on firms to maximize profits. Nonetheless, Florida's argument has won wide acclaim.

Belatedly, economic geographers came to embrace culture (Barnes, 2001; Martin and Sunley, 2001; Ettlinger, 2003; Gibson and Kong, 2005; Yeung, 2005). In part, economic geography's long-standing detachment from culture reflected its earlier infatuation with neoclassical economics, which views the economy as a black box utterly detached from the rest of society, as if it were devoid of social, political, economic (and spatial) origins and consequences. Economic and cultural geography – two major parts of a discipline renowned for the diversity of its theoretical views – suffered for decades in relative isolation of one another, as if the economy and culture had little to do with one another. Fortunately, what have long been distinct subdisciplines, each with its own body of theory, vocabulary, methodology, and topics of inquiry, recently have increasingly blended into one another, an intersection fostered by their mutual interest in issues of social relations, power, and location. Barnes (2005) explicitly seeks to dissolve the boundaries between the cultural and the economic by replacing them with a hybrid, one that offers the possibility of escaping traditional dualisms. Thus, as he puts it (p. 73), "The task of a hybrid economic geography should not be simply to reverse the binary and make culture primary, and the economy secondary. Rather, it should be to dissolve the binary altogether." As a result, economic geographers came to emphasize culture as a complex set of relations every bit as important as putatively 'economic' factors in the structuring of economic landscapes.

Another arena in which the inseparability of the economic and the cultural is made profoundly evident is the geography of consumption. When rescued from neoclassical economics, consumption offers an ideal opportunity to view the intersections of social relations, culture and ideology, and space. Not surprisingly, a fecund geographical literature on consumption and shopping has sprouted (Mansvelt, 2005; Leslie, 2009; Goodman et al., 2010), much of it pointing to how it shapes consumers and spaces. Geographies of food play an especially important role in this regard (Wrigley, 2002). In particular when linked to commodity chains, consumption offers an ideal pedagogic vehicle for exploring the politics of everyday life, identity, and the body (Hartwick, 2000).

A major concern of theorizations of economic landscape is the formation and role of clusters of economic activity (Vorley, 2008; Martin and Sunley, 2003; Cumbers and MacKinnon, 2004; Benneworth and Henry, 2004). Clusters represent the age-old theme of agglomeration economies in yet another reincarnation. Inspired by the turn to post-Fordism and attending rounds of vertical disintegration, clusters represent a variety of concentrated economic activity ranging from small, localized groups of manufacturing firms to enormous pools of producer services in global cities. Much of the search for the keys to their success hinged on the role of face-to-face contacts and the exchange of tacit knowledge (Storper and Venables, 2004). The analysis of clusters led economic geographers to emphasize more qualitative, contextual approaches to competitiveness, including the seminal role played by knowledge spillovers and positive externalities in the formation of 'learning regions.'

Like cultural and political geographers, economic geography continues to grapple with the multitude of issues and processes grouped under the term globalization. Dicken's (2011) architectonic volume *Global Shift*, which remains, after several decades and multiple editions, still the discipline's foremost summary of the topic. By now, the interpenetration of the local and the global (or 'glocalization') has become common place. Following the move to view places as networks, this literature decisively portrayed regional development in terms of globalized commodity chains, in which spatiality is unevenly and contingently produced through an intertwined series of both local and worldwide linkages (Amin, 2002; Sheppard, 2002; Coe et al., 2004).

Finally, economic, political, and cultural geographers have all wrestled with the thorny question of neoliberalism and its massive impacts around the world. David Harvey (2005a,b, 2006, 2011), still the doyen of Marxist theorization, has worked assiduously to unpack the dynamics of neoliberalism as both an economic and political project, one that reflects capitalism's incessant drive to recreate landscapes and reinvent itself periodically through the generation of crises, including the worldwide Great Recession that began in 2007.

Geographies of Cyberspace

Digital technologies have been central not only to the reconstruction of global capitalism over the last four decades, but also increasingly to the rhythms and contours of daily life. In December 2011, more than 2.25 billion people used the Internet, making it a tool of communications, entertainment, and other applications accessed by roughly 32% of the world's population (www.internetworldstats.com/stats.htm). For most users, these uses extend well beyond e-mail, the most common Internet use, to include bill payments and electronic banking; job and housing searches; stock trading; 'e-tail' shopping; searching for health information and news; online classes;

digital gambling; online video games; Internet telephony; hotel and airline reservations; chat rooms; electronic tax payments; downloading television programs, movies, digital music, and pornography; and popular sites and services such as YouTube, Facebook, and Google. In all these ways, and more, cyberspace offers profound real and potential effects on social relations, everyday life, culture, politics, and other social activities. Indeed, for rapidly rising numbers of people around the world, the 'real' and the virtual have become thoroughly interpenetrated. In this light, access to cyberspace is no longer a luxury, but a necessity. As its applications have multiplied, the Internet is having enormous impacts across the globe, including interpersonal interactions and everyday life, identity formation, retail trade and commerce, governance, and is affecting the structure and form of cities, in the process generating round upon round of non-Euclidean geometries in the context of a massive global wave of time–space compression.

By now, digital reality and everyday life for hundreds of millions of people have become so thoroughly fused that it is difficult, if not impossible, to disentangle them. In this context, simple dichotomies such as 'off-line' and 'online' fail to do justice to the diverse ways in which the 'real' and virtual worlds for hundreds of millions are interpenetrated. Yet for many others – the familiar litany of the poor, the undereducated, the ethnic minorities, and the socially marginalized – the Internet remains a distant, ambiguous world. Denied regular access to cyberspace by the inability to purchase a personal computer, the technical skills necessary to log on, or public policies that assume their needs will be magically addressed by the market, the information have-nots living in the economically advanced world are deprived of many of the essential skills necessary for a successful or convenient life (Crang et al., 2006). While those with regular and reliable access to the Internet drown in a surplus of information – much of it superfluous, irrelevant, or unnecessary – those with limited access have difficulty comprehending the opportunities it offers, the savings in time and money it allows, and the sheer convenience, entertainment value, and ability to acquire data from bus schedules to recipes to global news.

For many social media users, the self is increasingly constructed through their online interactions. In contrast to the prevailing Western model of subjectivity of the autonomous individual, digital media allow for a new form of sociability that greatly enhances the importance of relational ties, leading, arguably, to a different form of the self than the historically accepted view of the self-contained, autonomous individual whose conception largely minimizes social interactions. The argument hinges on the notion of the networked self, beings so immersed in digital social media that their online identities, personas, and reputations are as central to their lives as their off-line counterparts. Networked selves tend to live at the center of webs of digital ties that bind space in complex and often unpredictable ways, so that conventional geographies of everyday life have limited relevance to understanding their outlook and behavior. Following Adams (2005), the networked self in many respects is 'boundless,' that is, able to escape the physical and temporal limits of the human body. Indeed, following Haraway's famous cyborgian model of the self, theorizations of cyberspace have plunged into how computer software and hardware generate nonhuman agencies in which the digital and the real are seamlessly fused (Thrift and French, 2002; Dodge and Kitchin, 2005a,b, 2007).

Critical Cartography and GIS

One symptom of social constructivism's success in human geography is its penetration into the long-asocial worlds of cartography and GIS. This undertaking, which began in earnest in the 1990s, was closely associated with a shift in understanding in the nature of spatial representations. Traditional cartography and GIS relied heavily on a strict separation of observer and observed, sign and referent, facts and values, the representation is mirror of objective world, the correspondence theory of truth, and, not coincidentally Cartesian notions of space as given, not produced. In this reading, there is a seamless transition from the map creator's intent to the product to the reader/viewer's understanding, and representation is only technical problem in which interpretation is unproblematic. This perspective has been heavily criticized for denying the existence of an observer, the social context in which the production of spatial knowledge takes place, and creating a false sense of objectivity.

Language and representation were, of course, one of the great problematics of twentieth century social thought, with deep roots in philosophy and linguistics. Under the impetus of postmodernism (e.g., Derrida), traditional views began to unravel as both the creation of knowledge and its interpretation were increasingly resituated in social terms. Under the impetus of Foucauldian thought, the notion of discourse came to summarize the intimate connections between knowledge and power and how worldviews shape subjects by simultaneously enabling and constraining their understanding of the world in historically specific ways. Critical cartographers such as Denis Wood (1992, 2010) initiated a thorough-going deconstruction of maps as discourses, i.e., not simply as things but as embodiments of social relations. Such a move called attention not only to the social contexts and power interests that lay behind the creation of maps, but their effects and consequences, notably the naturalization of spatial relations. Maps, like all discourses, exist in a simultaneously determinant relationship with their contexts, helping to create the world that brought them into being.

Similarly, social constructivism decisively invaded the politically antiseptic world of GIS. Critics asserted that the subdiscipline that revolved around the technology had long attempted to act as a Trojan Horse to resmuggle empiricism back into the discipline. Naïve views could lead to digital panopticons and geoslavery (Dobson and Fisher, 2007). Inspired by the work of Pickles (1995), this process exposed GIS as a socially embedded technology (Sheppard, 2005; Schurrman, 2000, 2006), a shift with far-reaching consequences (Warf and Sui, 2010). Far from constituting an ostensibly objective view of reality, GIS was been discursively repositioned as a particular mode of geographing that privileges the quantitative over the qualitative, the observable over the nonobservable, form over process, and site characteristics over relational situation ones. As a result, the recent evolution of GIS has unveiled a fantastic zoo of new species, including, to take but a few examples, critical GIS (Sheppard, 2005b), participatory GIS (Elwood, 2006), volunteered geography (Goodchild, 2007), affective/emotional GIS

(Aitken and Craine, 2009), qualitative GIS (Cope and Elwood, 2009), feminist GIS (Kwan, 2002; McLafferty, 2005), queer GIS (Brown and Knopp, 2008), digiplaces (Zook and Graham, 2007a,b), GIS invoking indigenous knowledge (Robbins, 2003), and humanistic GIScience (Sui, 2004; Bodenhamer et al., 2010). In many ways, these developments reflect a highly productive engagement between the GIS community and social theorists and humanities scholars over the last decade, which resulted in studied attempts at 'pixelizing the social and socializing the pixel.'

The Social Construction of Nature

One largely unintended consequence of social theory's penetration of different segments of the discipline of geography has been the initiation of a gradual rapprochement between its human and physical branches, helping to heal a long-standing schism that plagued the field for a century or more (Hanson, 1999; Harden, 2012). In rejecting the traditional duality of 'nature' and 'culture,' the intersection of social theory and environmental analysis has given birth to a view often labeled the social construction of nature, a view that takes as its point of departure the notion that 'nature' does not exist independently of human activities nor can it be understood outside of social frames of reference (Castree and Braun, 2001; Castree, 2005; Bridge, 2011). Thus nature and society recursively shape one another both materially and discursively, so that attempts to differentiate them are doomed. The production of human geographies is inevitably also the production of nature. This process unfolds at multiple spatial scales, from the molecular (e.g., genetic engineering of crops) to the global (e.g., anthropogenic climate change).

Such a perspective injects a badly needed dose of political relevance into the analysis of environmental issues. Conflicts long seen as 'people versus nature,' such as deforestation, are repositioned as struggles among social groups (particularly classes), and intimately linked to the global and regional dynamics of regional inequality. Likewise, 'natural' hazards are not seen as natural, but closely tied to the social processes that generate differential vulnerability and susceptibility to floods, earthquakes, and other disasters, almost invariably along class, gender, and racial lines. Mounting concerns over environmental justice have politicized the analysis of health-related issues such as air quality and exposure to toxic wastes (Pulido, 2000). Finally, as anthropogenic climate change becomes increasingly visible as one of the world's most pressing social and environmental issues, human geographers have explored the political dynamics swirling around this issue (Demeritt, 2001; Wainwright, 2010).

Concluding Thoughts

Given the enormous heterogeneity of topics and subjects included within the broad domain of social theory and space, are there significant themes and commonalities that underpin this body of work? Human geography's embrace of social theory, largely originating with Foucault and encompassing various forms of social constructivism, has highly politicized the field, giving it great sensitivity to issues of power and social justice, injected a deep sense of morality. Much of the field self-consciously identifies with the socially and politically marginalized, including long-standing concerns regarding class, ethnicity, and gender as well as relatively newer sympathies for sexual minorities, indigenous peoples, the handicapped, animals, and others. Social constructivism has spilled beyond the confines of traditionally 'human' topics to inject these concerns into cartography, the analysis of GIS, and the social construction of nature. Given the unrelenting assault by neoliberalism in many arenas across the planet, these issues are decidedly nontrivial. One response has been the rise of geographies of empathy, caring, and responsibility (Lawson, 2007), including the adoption of cosmopolitan ideologies (Harvey, 2009; Warf, 2012). If these strategies make human geography more humane, then so much the better.

Abstract

Spatial cognition is central to *human thinking*, and *spatial language* is thus an important area of study, as it may reveal fundamental properties of human thought. Recent research has shown that spatial language is much more divergent across languages than had previously been thought, suggesting significant cultural patterning of spatial conceptualization. This article reviews spatial language cross-linguistically, sets out a typological framework for the language of space, and considers the relationship of spatial language to spatial cognition, in the context of extensive linguistic diversity in the spatial domain.

Spatial cognition is at the heart of much human thinking, as evidenced, for example, in the explanatory power of spatial metaphors and diagrams, and the explication of spatial concepts has played a key role in the development of Western mathematics and philosophy over two and a half millennia (see Jammer, 1954). It is therefore easy to assume that spatial notions form a robust, universal core of human cognition; this assumption has dominated the cognitive sciences (e.g., Miller and Johnson-Laird, 1976). But naive human spatial language turns out to vary significantly across languages, both in the way it is semantically organized and the way in which it is coded. This has major implications for how we should think about universals in human thought and language.

The Western intellectual tradition has provided an elaborate metalanguage for spatial concepts, but the conceptual underpinnings of naive human spatial language utilize only a small subset of these concepts. Moreover, there are many aspects of our spatial perception and motor control which utilize much richer and more precise representations of space than are coded in language. The study of the representation of space in language, and its relation to cognition, must therefore be treated as an empirical enterprise, and this article reports on the increasing body of cross-linguistic information about how different languages structure the spatial domain (see Levinson and Wilkins, 2006).

Space as a Semantic Domain

Languages tend not to treat space as a single, coherent semantic field in the same way that they treat, for example, color (q.v.), kinship (q.v.), or ethnobotany – rather, space is structured as a large semantic field with many distinct subdomains, each of which is closely structured (and often varies considerably across languages). Nearly all languages have 'where' questions that cover the entire field (i.e., with the same or morphologically related forms for 'where-to,' 'where-from,' and 'where-at') and describe the location of one object primarily with respect to another. But beyond these general properties, spatial expressions are structured in distinct subdomains, notably topology, frames of reference, and motion, with place names and spatial deixis as complementary areas. These subdomains cross-cut in certain ways (e.g., frames of reference may play a role in motion description), but because they have their own internal organization they need to be kept analytically distinct.

Although the philosophical and scientific literature gives us many different ways to talk about space, natural languages tend to structure spatial description more in accord with the ideas of Leibniz than of Newton. That is, location is thought about as the place of one thing relative to another (rather than, as in Newtonian thinking, as specifications in the coordinates of an infinite, abstract three-dimensional 'box'). We will call the object to be located the 'figure' (F), and the object with respect to which the location is specified the 'ground' (G); other equivalent terms in the literature are 'theme' versus 'relatum' or 'trajector' versus 'landmark.' As Talmy (1983) noted, a good ground or landmark object is larger than and less mobile than the figure object to be located. The problems of location specification then largely boil down to the following functional considerations:

1. Where figure F and ground G are contiguous or coincident, a static F may be said to be 'at G.' Where G is large, it can be subdivided, so that F can be said to be 'at the X-part of G.' This is, roughly, the subdomain of topology.
2. Where F and G are separated in space, the problem is to specify an angle or direction from G in which F can be found (the search domain). This involves a coordinate system of some kind – a 'frame of reference' – of which there are three main types found in languages.
3. Where F is in motion, two kinds of ground are especially relevant: the source and the goal of the motion. To indicate the progression of motion (i.e., the increase or decrease of distance from a ground), motion can be specified as 'F is moving toward goal G' or 'F is moving from source S.' In addition, motion can be thought of as bringing about, or destroying, a topological relation, as in 'F moves into/out of G.' But to indicate a direction or vector of motion, both S and G must be specified, or a coordinate system of the kind mentioned in (2) utilized. Of course, motion can also be specified as taking place within a location, in which case the systems in (1) and (2) can be utilized.

These functional distinctions give us a number of cleavages: stasis (or location) versus kinesis (or motion), nonangular topological relationships versus angular relations specified in

Figure 1 Crosscutting subdomains of spatial language.

frames of reference, with potentially cross-cutting domains as shown in Figure 1.

Some further details in Figure 1, like the three frames of reference, are described below. But the two subfields that have not been discussed further need to be mentioned here. One is *deixis*, which concerns the way in which the location of the speech participants can constitute a special ground or landmark (as in *here*), which then makes interpretation dependent on determining that location (as in *He used to come here*). Languages universally seem to provide a structured set of deictic elements with distinctions that are often spatial (demonstratives like 'this' vs 'that,' adverbs like 'here' vs 'there'). Deictic anchoring of spatial expressions is, however, often implicit or pragmatic: *the local pub* implies a pub close to some reference point, which unless specified, is taken to be the place of speaking.

A second subfield not treated further here is toponymy, or systems of place names. Place names have been much investigated from an historical point of view; since they are highly conservative they reveal a great deal about the locations of ancient languages and peoples. However, the theory and cross-linguistic typology of place names – e.g., why some are descriptive, others not – is hardly developed at all (see e.g., Hunn, 1993).

Universals and Variation in the Semantic Parameters in Spatial Subdomains

In this section, the semantic parameters involved in spatial description in two major subdomains are described to illustrate some of the different ways in which languages structure the spatial domain.

Topology

The subdomain of topology, as mentioned, concerns contiguous relations between figure and ground. The term is potentially misleading – topology proper is a branch of geometry concerned with constancies under continuous distortions such as stretching, but, following Piaget (Piaget and Inhelder, 1956), it is used in studies of spatial language to describe the sort of spatial relations covered by the English prepositions *on*, *in*, and *at* (Herskovits, 1986). These spatial terms are among the earliest learnt by Western children, and it has therefore been supposed that they form a universal innate core of spatial notions. However, cross-linguistic studies show that universal semantic concepts are only to be found at a more abstract level. Take, for example, the spatial relations covered by English *on*, as in *The cup is on the table*, *The picture is on the wall*, or *The fresco is on the ceiling* – clearly the term *on* covers a wide area which is already subdivided in the adpositions (prepositions or postpositions) of many other European languages. Some languages (like Japanese) conflate 'on' relations with 'over' relations (as in *The light is over the table*) in their adpositions; others (like Yukatek Maya) even include 'under' relations as well (as in *The ball is under the table*). A detailed analysis of a dozen languages from different families suggests that universal semantic concepts in this domain lie at a more atomic level (Levinson and Wilkins, 2006). If we think of the core prototype of English *on* as consisting of the notion of vertical superposition of figure over ground, with a horizontal ground supporting a nonattached figure, then the kind of notions that look universal are at the level of 'vertical superposition,' 'contact,' 'horizontal supporting surface,' and (non)'attachment.' Clearly, these more abstract atomic concepts can be rearranged in many different ways to constitute the semantic relations expressible in an individual language (Levinson and Meira, 2003).

Topological relations are coded in the European languages primarily in adpositions or case, but, as we shall see, these are not the only possibilities – some languages code topological relations entirely in nouns or verbs.

Frames of Reference

Linguists have presumed that there are two main frames of reference, which are often called 'deictic' and 'intrinsic,' and which can be illustrated by the ambiguity of the sentence *The boy is behind the bus* – either the bus is between the boy and us ('deictic') or he is at the rear of the bus ('intrinsic'). Psychologists have long known, however, that on the vertical dimension our perceptual systems use three frames of reference against which to measure uprightness: an object-centered frame, a viewer-centered frame, and an environmental frame. Cross-linguistic research shows that in fact these three frames of reference, which we will call the intrinsic, the relative, and the absolute frame, respectively, may be used on the horizontal plane too (Levinson, 1996). These three frames appear to be universally available, yet not all languages make systematic use of them all – some use the absolute frame, others the relative frame, while most use the intrinsic frame, and some use all three. The main universal constraint appears to be that the relative frame is dependent on the possession of the intrinsic frame.

The intrinsic frame of reference, as its name implies, has to do with the intrinsic parts of ground objects. Recollect that frames of reference are coordinate systems that specify angles or directions from a landmark. One way to achieve this is to designate a side or facet of an object, so that the figure can be said to be located on an axis drawn from the center of the object through the designated side. Most languages provide a vocabulary for parts of objects, but the ways in which they partition objects can be very variable. In English, for example, the criteria

for assigning the *front* of an object involve a complex mix of functional and orientational information: the front of a bus is the direction in which it canonically moves, the front of a building is the side in which it is normally entered, and the front of a television the side designed to be watched. In English the *top* of a bottle remains the top even when tipped over, but in other languages (like Zapotec) a more strictly orientational approach may assign the 'top' to whatever side is currently uppermost. Alternatively (as in Tzeltal), the assignment may rely entirely on the internal axial geometry of the object, so that, for example, the 'face' of an object may be a flat side on a secondary axis, even if normally this is undermost. What all these systems have in common is that they provide a system of designated sides to objects which is independent of the position of the viewer, and (apart from the vertical axis) independent of an environmental orientation. How they achieve this differs not only in detail but also in fundamentals.

Another way of obtaining angular distinctions on the horizontal plane is to use the body axes of the viewer. We can then say that something is, for example, to the 'left' of something else in the visual field. Full versions of such systems use a left/right axis and an orthogonal front/back axis, but again the way in which they map bodily axes onto the ground object is very variable. Although these systems are often called 'deictic' in the literature, this is misleading – they typically have a deictic center but they do not have to (as in *He kicked the ball to the left of the goal*), and the other two frames of reference can also have deictic centers (e.g.,'It is north of us,' 'It is at my left hand'). Relative frames of reference are, here, said to be 'relative' because they are relative to the body axes of some observer. Some languages translate the bodily coordinates onto the ground object without rotation; in such languages (like Hausa) *The boy is to the left of the tree* means just what it does in English, but *The boy is in front of the tree* means what in English is described as *The boy is behind the tree*. In contrast, some languages rotate the axes, so that the front of the tree is toward us, but the left of the tree is what in English we would call its right (this is probably a minority option, but is found in some dialects of Tamil). Some languages reflect the axes, as in English, so that left and right remain in the same directions as the viewer's body, but front and back are reversed or 'flipped' over.

Notice that terms like 'front' and 'back' and 'left' and 'right' also have intrinsic interpretations (as in *He's sitting at the chairman's left*), and for that reason ambiguities arise of the kind illustrated above with *The boy is behind the bus*. Relative systems are based on the intrinsic sides of humans, and probably arise as extensions of an intrinsic system to objects (like trees or balls) which resist the assignment of named sides. Hence the implicational relation: all relative systems are associated with intrinsic systems, but the possession of an intrinsic system does not necessarily imply the use of a relative one. Relative systems had been thought to be universal, but in fact it turns out that perhaps as many as a third of the world's languages do not employ them, instead making use of absolute systems.

Absolute systems rely on environmental gradients or 'geocentric' coordinates. Such systems use absolute directions, or fixed bearings, a bit like English *north*, but unlike in English, they are often used on all scales (as in *The cup to the north of yours is mine*, or even *There's a spider on your northern leg*), completely replacing the need for relative systems. There are many different varieties of absolute systems. Some of them (as in Australian Aboriginal languages) are fully abstract cardinal direction systems, with terms that may gloss 'north,' 'south,' etc., but which denote quadrants or arcs of specific angle, and are often based on bearings rotated from our cardinal directions. To use a system of this kind, speakers must always orient themselves precisely, using multiple environmental clues (wind directions, solar angles, sidereal ecliptics, landscape features, and the like). Other systems are based more directly on one major environmental cue, like prevailing winds (as in languages of the Torres Straits), river drainage (as in Alaska), a seaward/landward distinction (as in many Oceanic languages), or prevailing slopes in mountainous terrain (as in the Himalayas). For example, Tenejapan Tzeltal uses an 'uphill,' 'downhill,' 'across' system, based on the general lay of the land in the mountainous territory of Tenejapa (Chiapas, Mexico), but the system has been abstracted from the terrain to provide a fixed orientation, so that the bearings remain constant outside the territory. Many systems use fixed orthogonal axes, but not all; for example, the Austronesian languages in the Pacific islands typically use the monsoon winds as the basis for one axis, but an inland-sea opposition as the basis for another axis; as one moves around the island, the angles between the axes constantly change.

It is important to note that there are cognitive consequences of relying on an absolute frame of reference for routine spatial description on all scales. Communication using such an absolute system requires that speakers' mental computations are adapted to enable constant background tracking of the coordinate system(s) and 'dead-reckoning,' or updating of speakers' locations as they move through the landscape (Levinson, 2003). Various cultural practices will support this background tracking (e.g., absolutely oriented gestures, attention to movements of the sun, shadows, and distant landmarks). Studies on the use of pointing gestures in cultures where absolute systems dominate in everyday use have contributed greatly to our understanding of how spatial frames of reference are invoked, communicated, and switched in conversational interaction, and provided important insights into the cognitive background to absolute systems (e.g., Levinson, 1997; Haviland, 2000, 2003; Kita et al., 2001; Le Guen, 2011). They have shown that gesture is deeply integrated into the system of directional reference, making it clear that these are not simply linguistic systems but broader communicative ones.

This raises the question of how children learn to use such apparently cognitively demanding systems. There have been a number of studies of children's acquisition of absolute systems (de León, 1994; Brown, 2001; Brown and Levinson, 2000, 2009; Cablitz, 2002; Dasen and Mishra, 2010). These have generally found that children master the basics of their absolute system relatively early – by the age of 6 or 7 – compared with the acquisition of projective left/right in European children which is often not fully mastered till age 11 (Piaget and Inhelder, 1956). This result is consonant with other work on child spatial language showing that children's language use reveals very early sensitivity to language-specific semantic differences, adapting to the local system of spatial categories from the beginning (e.g., Bowerman, 1996; Bowerman and Choi, 2001). This is evidence that in this domain the child must *construct* the relevant categories; these are not given by innate endowment, contrary to what had been argued for the spatial domain.

How Spatial Distinctions Are Coded in Language Forms

Much of the literature gives the impression that spatial distinctions are primarily coded in adpositions, as in the prepositions of English. In fact, in most languages spatial information is distributed throughout the clause. Some languages have a score or more local cases (nominal suffixes) covering roughly the same distinctions as English prepositions (e.g., Finnish or the NE Caucasian language Avar). Other languages use a combination of case and adposition (as in Tamil), or case and spatial nominal (as in many Australian languages). Special classes of spatial nominals (e.g., 'front,' 'back,' and 'side') do a lot of the work in isolating languages like Chinese, and they play special roles in other languages (cf *front* in the English complex preposition *in front of*, and *north* in the adverbial use *He went north*). Many spatial oppositions are made constructionally, as when German prepositions like *auf* take the dative to indicate location but the accusative to indicate motion toward a goal.

Finally, verbs play a crucial role in spatial description. In the case of motion, there is often a special form class of motion verbs, and languages tend to conflate motion with manner (as in English *crawl*) or with direction or 'path' (as in Spanish *salir*: 'to go out'), but not generally both (Talmy, 1983, 2000). In many languages (e.g., Dutch), there is a small set of contrasting verbs (often derived from posture verbs) used to describe static location, encoding properties of the figure or ground, or both. Some languages have a larger set (as in Tzeltal), and in this case most of the semantic load is taken by the verbs, which may encode such specific details as 'be located in a bowl-shaped container' (Brown, 1994). Where the verbal component of locative statements is semantically specific in this way, it can impose a spatial categorization on objects in the world (e.g., long.thin.vertically.upright versus horizontally.extended.in.three.dimensions) that is depicted in gestures used when talking of putting and taking things; this provides a window on the possible cognitive effects of these categorizations (Ameka and Levinson, 2007). Even verbs without such spatial specificity – e.g., verbs of motion like 'go,' 'come,' 'enter,' and 'exit' (Wilkins and Hill, 1995; Kita, 1999), and of caused motion or placement verbs like 'put' and 'take' (Kopecka and Narasimhan, 2011; Slobin et al., 2011) display considerable cross-linguistic variability in their semantics. And even closely related languages may differ in their 'basic locative construction,' for example, in whether a preposition or a verb provides the unmarked construction for describing locative relations (as in Mayan languages; see Bohnemeyer and Brown, 2007).

In conclusion, it is clear that spatial concepts form a complex semantic field made up of structured linguistic subdomains. The semantic parameters involved may ultimately have a universal base, but the way in which the semantic subdomains are organized displays considerable cross-linguistic variation. There is also cross-linguistic variation in the way in which such distinctions are encoded in the form classes of languages.

There is now a great deal more information about spatial semantics in different languages than was available 30 years ago. This includes detailed descriptions of the language of space in different languages (e.g., de León and Levinson, 1992; Svorou, 1993; Dirven and Pütz, 1996; Danziger, 1998; Levinson and Wilkins, 2006), and areal surveys of spatial language (e.g., Levinson and Haviland, 1994 for Mayan languages; Senft, 1997 for Oceanic languages; and O'Meara and Pérez Báez, 2011 for Mesoamerican languages), as well as a number of cross-linguistic comparisons of spatial language in particular semantic domains, for example, landscape (Burenhult and Levinson, 2008), body parts (Majid et al., 2006), locative verbs (Ameka and Levinson, 2007), placement verbs (Kopecka and Narasimhan, 2011), and space/time metaphors (e.g., Majid et al., 2012). There is therefore much more visibility for the range of cross-linguistic variation that exists in the spatial domain and in the extension of spatial meanings to more abstract domains like time, kinship, and social relations. In addition, we now have some initial evidence for distinct patterns of neural activation in the brain for different frames of reference (Janzen et al., 2012).

This linguistic variation is especially interesting given the centrality of spatial concepts in human thinking – and indeed it has been shown that linguistic differences in frames of reference can make a difference to how humans memorize and reason nonlinguistically about space (Levinson, 1996, 1997, 2003; Pederson et al., 1998; Majid et al., 2004; Haun et al., 2011). There is robust evidence for several unrelated languages and cultures (ranging from Mexico to Australia to Africa to Nepal and Bali) that peoples' frame of reference usage in nonlinguistic cognition matches that of their language use. This linguistic variation and the associated interactional and cultural properties pose questions that are central to our understanding of how language and cognition are interrelated, how they are embedded in cultural practices, and how children's cognitive development may be shaped while they are learning a language.

Spatial Analysis in Geography

Manfred M Fischer, Vienna University of Economics and Business, Vienna, Austria

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article reviews some of the special properties of spatial data and the ways in which these properties have influenced developments in spatial data analysis. The discussion focuses on exploratory and model-driven (confirmatory) modes of analyzing spatial data, in particular spatial point patterns and area data, which occupy a prominent position in social science research. The article concludes with a brief discussion of some key areas in which the field of spatial data analysis has been growing in recent years.

The proliferation and dissemination of digital spatial databases, coupled with ever-wider geographic information systems (GISs) use, is stimulating increasing interest in spatial analysis from outside the spatial sciences. Scholars have begun to recognize that including the spatial dimension in social science research sometimes yields different and more meaningful results than analysis that ignores it.

Spatial analysis is a research paradigm that provides a unique set of techniques and methods for analyzing events – events in a very general sense – that are located in geographical space. Spatial analysis involves spatial modeling, which includes models of location allocation, spatial interaction, spatial choice and search, spatial optimization, and space–time (for an account of the diversity of approaches, see Fischer and Getis, 2010). Other articles in the encyclopedia take up these models (e.g., *see* Location Theory; Spatial Interaction Models; Spatial Optimization Models; Spatial–Temporal Modeling); this article concentrates on spatial data analysis, the heart of spatial analysis. The discussion here is on exploratory and model-driven (confirmatory) modes of analyzing and modeling spatial data (see **Table 1**).

Spatial Data and the Tyranny of Data

In essence, spatial data analysis focuses on detecting patterns and exploring and modeling relationships between such patterns in order to understand processes responsible for observed patterns. In this way, spatial data analysis emphasizes the role of space as a potentially important explicator of socioeconomic systems and attempts to enhance understanding of the working and representation of space, spatial patterns, and processes.

Spatial Data and Data Types

Empirical studies in the spatial sciences routinely employ data for which locational attributes are an important source of information. Such data characteristically consist of one or a few cross sections of observations for either micro-units such as individuals (households, firms) at specific points in space, or aggregate spatial entities such as census tracts, electoral districts, regions, provinces, or countries. Observations such as these, for which the absolute location and/or relative positioning (spatial arrangement) is explicitly taken into account, are termed 'spatial data.'

In the socioeconomic realm, points, lines, and areal units are the fundamental entities for representing spatial phenomena. This form of spatial referencing is also a salient feature of GIS (e.g., *see* Geographic Information Systems; Spatial Data Infrastructures). Three broad classes of spatial data can be distinguished:

1. *Object data*, where the objects are either points (spatial point patterns or locational data, that is, point locations at which

Table 1 Popular techniques and methods in spatial data analysis

	Exploratory spatial data analysis	*Model-driven spatial data analysis*
Object data		
Point pattern	Quadrat methods Kernel density estimation Nearest neighbor methods *K*-function analysis	Homogenous and heterogenous Poisson process models and multivariate extensions
Area data	Visualization methods and mapping such as linking and brushing views and cartograms Global and local spatial autocorrelation statistics	Spatial regression models: Spatial lag and spatial error models Spatial Durbin model
Field data	Choropleth maps Spatial cluster detection statistics	Trend surface models Semivariogram and covariance models
Spatial interaction data	Exploratory techniques for representing such data Techniques to uncover evidence of hierarchical structure in the data such as graph-theoretic and regionalization techniques	Poisson spatial interaction models Spatial filtering versions of spatial interaction models

events of interest have occurred) or areas (area or lattice data, defined as discrete variations of attributes over space).
2. *Field data* (also termed geostatistical or spatially continuous data), that is, observations associated with a continuous variation over space, given values at fixed sampling points.
3. *Spatial interaction data* (sometimes called link or flow data), consisting of measurements each of which is associated with a link or pair of locations representing points or areas.

The analysis of spatial interaction data has a long and distinguished history in the study of a wide range of human activities, such as transportation movements, migration, and the transmission of information (see Fischer and Wang, 2011, for a discussion). Field data play an important role in the environmental sciences, but are less important in the social sciences. This article, therefore, focuses on object data, the most appropriate perspective for spatial analysis applications in the social sciences. Object data include observations for micro-units at specific points in space, that is, spatial point patterns, and/or observations for aggregate spatial entities, that is, area data.

Of note is that point data can be converted to area data, and area data can be represented by point reference. Areas may be regularly shaped such as pixels in remote sensing or irregularly shaped such as statistical reporting units. When divorced from their spatial context, such data lose value and meaning. They may be viewed as single realizations of a spatial stochastic process, similar to the approach taken in the analysis of time series.

The Tyranny of Data

Analyzing and modeling spatial data present a series of problems; solutions to many of which are obvious, while solutions to others require extraordinary effort. Data exercise a power that can lead to misinterpretation and meaningless results; therein lies the tyranny of data.

Quantitative analysis crucially depends on *data quality*. Good data are reliable, contain few or no mistakes, and can be used with confidence. Unfortunately, nearly all spatial data are flawed to some degree (e.g., *see* Spatial Data). Errors may arise in measuring both the location and attribute properties but may also be associated with computerized processes responsible for storing, retrieving, and manipulating spatial data. The solution to the data quality problem is to take the necessary steps to avoid having faulty data determining research results.

The *particular form* (i.e., size, shape, and configuration) *of the spatial aggregates* can affect the results of the analysis to a varying, usually unknown, degree, as evidenced in various types of analysis (e.g., Openshaw and Taylor, 1979; Baumann et al., 1983). This problem generally has become recognized as the modifiable areal unit problem (MAUP), the term stemming from the fact that areal units are not 'natural' but usually arbitrary constructs. For reasons of confidentiality, social science data (e.g., census data) are not often released for the primary units of observation (individuals), but only for a set of rather arbitrary areal aggregations (enumeration districts or census tracts). The problem arises whenever area data are analyzed or modeled and involves two effects. One effect derives from selecting different areal boundaries while holding the overall size and the number of areal units constant (the zoning effect). The other effect derives from reducing the number but increasing the size of the areal units (the scale effect). There is no analytical solution to the MAUP, but questions of the following kind have to be considered in constructing an areal system for analysis: What are the basic spatial entities for defining areas? What theory guides the choice of spatial scale? Should the definition process follow strictly statistical criteria and merge basic spatial entities to form larger areas using some regionalization algorithms (see Wise et al., 1996)? These questions pose daunting challenges.

In addition, *boundary and frame effects* (i.e., the geometric structure of the study area) may affect spatial analysis and the interpretation of results. These problems are considerably more complex in time-series analyses. Although several techniques, such as refined *K*-function analysis, take the effect of boundaries into account, there is a need to study boundary effects more systematically.

An issue that has been receiving increasing attention relates to the suitability of data. If the data, for example, are available only at the level of spatial aggregates, but the research question is at the individual respondent level, then the *ecological fallacy* (ecological bias) problem arises. Using area-based data to draw inferences about underlying individual-level processes and relationships poses considerable risks. This problem relates to the MAUP through the concept of spatial autocorrelation.

Spatial autocorrelation (also referred to as spatial dependence or spatial association) in the data can be a serious problem (e.g., *see* Spatial Autocorrelation), rendering conventional statistical analysis unsafe and requiring specialized spatial analytical tools. This problem refers to situations where the observations are nonindependent over space. That is, nearby spatial units are associated in some way. Sometimes this association is due to a poor match between the spatial extent of the phenomenon of interest (e.g., a labor or housing market) and the administrative units for which data are available. Other times it is due to a spatial spillover effect. The complications are similar to those found in time-series analysis, but are exacerbated by the multidirectional, two-dimensional nature of dependence in space rather than the unidirectional nature in time. Avoiding the pitfalls arising from spatially correlated data is crucial to good spatial data analysis, whether exploratory or confirmatory. Several scholars even argue that the notion of spatial autocorrelation is at the core of spatial analysis (e.g., Tobler, 1979). No doubt much of current interest in spatial analysis is directly derived from the monograph of Cliff and Ord (1973) on spatial autocorrelation, which opened the door to modern spatial analysis.

Pattern Detection and Exploratory Analysis

Exploratory data analysis (EDA) is a collection of techniques for summarizing data properties, detecting patterns in data, identifying unusual or interesting properties in data, detecting errors, and formulating hypotheses from data. Many such techniques emphasize graphical views of the data that are designed to highlight particular features and allow the analyst

to detect patterns, relationships, outliers, and so forth. Exploratory spatial data analysis (ESDA), an extension of EDA (Haining, 1990; Cressie, 1993), is geared especially to dealing with the spatial aspects of data.

Exploratory Techniques for Spatial Point Patterns

Point patterns arise when the important variable to be analyzed is the location of events. At the most basic level, the data comprise only the spatial coordinates of events. They might represent a wide variety of spatial phenomena, such as cases of disease, crime incidents, pollution sources, or locations of stores (e.g., *see* Spatial Pattern, Analysis of). The visualization of spatial locations (spatial point patterns) can provide valuable insights into such data.

Research typically concentrates on whether the proximity of particular point events, their location in relation to each other, represents a significant (i.e., nonrandom) pattern. Exploratory spatial point pattern analysis is concerned with exploring the first- and second-order properties of spatial point pattern processes. First-order effects relate to variation in the mean value of the process (a large-scale trend), while second-order effects result from the spatial correlation structure or the spatial dependence in the process.

Three types of methods are important: quadrat methods, kernel estimation of the intensity of a point pattern, and distance methods. Quadrat methods involve collecting counts of the number of events in subsets of the study region. Traditionally, these subsets are rectangular (thus the name 'quadrat'), although any shape is possible. The reduction of complex point patterns to counts of the number of events in quadrats and to one-dimensional indices results in a considerable loss of information. There is no consideration of quadrat locations or of the relative positions of events within quadrats. Thus, most of the spatial information in the data is lost. Quadrat counts destroy spatial information, but they give a global idea of subregions with high or low numbers of events per area. For small quadrats, more spatial information is retained, but the picture degenerates into a mosaic with many empty quadrats.

Estimating the intensity of a spatial point pattern is very like estimating a bivariate probability density, and bivariate kernel estimation can be adapted easily to give an estimate of intensity. Choice of the specific functional form of the kernel presents little practical difficulty. For most reasonable choices of possible probability distributions, the kernel estimate will be very similar for a given bandwidth. The bandwidth determines the amount of smoothing. There are techniques that attempt to optimize the bandwidth given the observed pattern of event location.

A risk underlying the use of quadrats is that any spatial pattern detected may be dependent upon the size of the quadrat. In contrast, distance methods make use of precise information on the locations of events and have the advantage of not depending on arbitrary choices of quadrat size or shape. Nearest neighbor methods reduce point patterns to one-dimensional nearest neighbor summary statistics (Dacey, 1960; Getis, 1964). But only the smallest scales of patterns are considered. Information on larger scales of patterns is unavailable. These statistics indicate merely the direction of departure from complete spatial randomness (CSR). The empirical *K*-function, a reduced second-moment measure of the observed process, provides a vast improvement over nearest neighbor indices (Ripley, 1977; Getis, 1984). It uses the precise location of events and includes all event–event distances, not just nearest neighbor distances, in its estimation. Care must be taken to correct for edge effects. *K*-function analysis can be used not only to explore spatial dependence but also to suggest specific models to represent it and to estimate the parameters of such models. The concept of *K*-functions can be extended to the multivariate case of a marked point process (i.e., locations of events and associated measurements or marks) and to the time–space case.

Exploratory Analysis of Area Data

Exploratory analysis of area data is concerned with identifying and describing different forms of spatial variation in the data. Special attention is given to measuring spatial association between observations for one or several variables. Spatial association can be identified in a number of ways, rigorously by using an appropriate spatial autocorrelation statistic (Cliff and Ord, 1981), or more informally, for example, by using a scatter plot and plotting each value against the mean of neighboring areas (Haining, 1990).

In the rigorous approach to spatial autocorrelation, the overall pattern of dependence in the data is summarized in a single indicator, such as Moran's *I* and Geary's *c*. While Moran's *I* is based on cross-products to measure value association, Geary's *c* employs squared differences. Both require the choice of a spatial weight or contiguity matrix that represents the topology or spatial arrangement of the data and hence our understanding of spatial association. Getis (1991) has shown that these indicators are special cases of a general formulation (called 'gamma') defined by a matrix representing possible spatial associations (the spatial weight matrix) among all areal units, multiplied by a matrix representing some specified nonspatial association among the areas. The nonspatial association may be a social, economic, or other relationship. When the elements of these matrices are similar, high positive autocorrelation arises. Spatial association specified in terms of covariances leads to Moran's *I*, specified in terms of differences to Geary's *c*.

These global measures of spatial association can be used to assess spatial interaction in the data and can be visualized easily by means of a spatial variogram, a series of spatial autocorrelation measures for different orders of contiguity. A major drawback of global statistics of spatial autocorrelation is that they are based on the assumption of spatial stationarity, which implies *inter alia* a constant mean (no spatial drift) and constant variance (no outliers) across space. This was useful in the analysis of small data sets characteristic of pre-GIS times but is not very meaningful in the context of thousands or even millions of spatial units that characterize current, data-rich environments.

In view of increasingly data-rich environments, a focus on local patterns of association (hot spots) and an allowance for local instabilities in overall spatial association recently has been suggested as a more appropriate approach. Examples of techniques that reflect this perspective are the various geographical analysis machines developed by Openshaw and co-workers (e.g., Openshaw et al., 1990), the Moran scatter plot (Anselin, 1996), and the distance-based G_i and statistics of Getis and Ord (1993). This last has gained wide acceptance.

These G-indicators can be calculated for each location i in the data set as the ratio of the sum of values in neighboring locations (defined to be within a given distance or order of contiguity) to the sum over all the values. The two statistics differ with respect to the inclusion of the value observed at i in the calculation (included in, or not included in, G_i). They can be mapped easily and used in an exploratory analysis to detect the existence of pockets of local nonstationarity, to identify distances beyond which no discernible association arises, and to find the appropriate spatial scale for further analysis (e.g., *see* Spatial Association, Measures of).

No doubt, ESDA provides a useful means to generate insights into global and local patterns and associations in spatial data sets. The use of ESDA techniques, however, generally is restricted to expert users interacting with the data displays and statistical diagnostics to explore spatial information and to fairly simple, low-dimensional data sets. In view of these limitations, there is a need for novel exploration tools sufficiently automated and powerful to cope with the data richness–related complexity of exploratory analysis in spatial data environments.

Model-Driven Spatial Data Analysis

ESDA is a preliminary step in spatial analysis to more formal modeling approaches. Model-driven analysis of spatial data relies on testing hypotheses about patterns and relationships, utilizing a range of techniques and methodologies for hypothesis testing, the determination of confidence intervals, estimation of spatial models, simulation, prediction, and assessment of model fit. Upton and Fingleton (1985), Anselin (1988), Griffith (1988), Haining (1990, 2003), Cressie (1993), Bailey and Gatrell (1995), and more recently LeSage and Pace (2009) and Fischer and Wang (2011) have helped to make model-driven spatial data analysis accessible to a wide audience in the spatial sciences.

Modeling Spatial Point Patterns

Spatial point pattern analysis grew out of a hypothesis testing and not out of the pattern recognition tradition. The spatial pattern analyst tests hypotheses about the spatial characteristics of point patterns. Typically, CSR represents the null hypothesis against which to assess whether observed point patterns are regular, clustered, or random. The standard model for CSR is that events follow a homogenous Poisson process over the study region, that is, events are independently and uniformly distributed over space, equally likely to occur anywhere in the study region, and not interacting with each other.

Various statistics for testing CSR are available. Nearest neighbor tests have their place in distinguishing CSR from spatially regular or clustered patterns, but little is known from nearest neighbor tests about the nature of the regular or clustered patterns when CSR does not hold. The K-function may suggest a way of fitting alternative models. Correcting for edge effects, however, might provide some difficulty. The distribution theory for complicated functions of the data can be intractable even under the null hypothesis of CSR. Monte Carlo tests are a way around this problem.

If the null hypothesis of CSR is rejected, the next obvious step in model-driven spatial pattern analysis is to fit some alternative (parametric) model to the data. Departure from CSR is typically toward regularity or clustering of events. Clustering can be modeled through a heterogenous Poisson process, a doubly stochastic point process, or a Poisson cluster process arising from the explicit incorporation of a spatial clustering mechanism. Simple inhibition processes can be utilized to model regular point patterns. Markov point processes can incorporate both elements through large-scale clustering and small-scale regularity. After a model has been fitted (usually via maximum likelihood or least squares using the K-function), diagnostic tests have to be performed to assess its goodness of fit. Inference for the estimated parameters is often needed in response to a specific research question. The necessary distribution theory for the estimates can be difficult to obtain, in which case approximations may be necessary. If, for example, clustering is found, one may be interested in the question of whether particular spatial aggregations, or clusters, are associated with proximity to particular sources of some other factor. This leads to multivariate point pattern analysis, a special case of marked spatial point process analysis. For further details, see Cressie (1993).

Modeling Area Data

Linear regression models constitute the leading modeling approach for analyzing social and economic phenomena. But conventional regression analysis does not take into account problems associated with possible cross-sectional correlations among observational units caused by spatial dependence. Two forms of spatial dependence among observations may invalidate regression results: spatial error dependence and spatial lag dependence.

Spatial error dependence might follow from measurement errors such as a poor match between the spatial units of observation and the spatial scale of the phenomenon of interest. Presence of this form of spatial dependence does not cause ordinary least squares (OLS) estimates to be biased, but it affects their efficiency. The variance estimator is downward biased, thus inflating the R^2. It also affects the t- and F-statistics for tests of significance and a number of standard misspecification tests, such as tests for heteroskedasticity and structural stability. To protect against such difficulties, one should use diagnostic statistics to test for spatial dependence among error terms and, if necessary, take action to properly specify the spatially autocorrelated residuals. Typically, dependence in the error term is specified as a spatial autoregressive or as a spatial moving average process. Model parameters of such regression models are usually estimated by nonlinear maximum likelihood methods (Cliff and Ord, 1981; Anselin, 1988).

In the second form of spatial dependence, spatial autocorrelation is attributable to spatial interactions in data. This form may be caused, for example, by significant spatial externalities of a socioeconomic process under study. To specify a regression model involving spatial interaction, one must incorporate the spatial dependence into the covariance structure either explicitly or implicitly by means of an autoregressive and/or moving average interaction structure. This constitutes the model identification problem that is usually carried out using

the correlogram and partial correlogram. A number of spatial regression models, that is, regression models with spatially lagged dependent variables (spatial autoregressive models), have been developed that include one or more spatial weight matrices that describe the many spatial associations in the data. The models incorporate either a simple general stochastic autocorrelation parameter or a series of autocorrelation parameters, one for each order contiguity (see Cliff and Ord, 1981; Anselin, 1988; LeSage and Pace, 2009).

To avoid biased and inconsistent OLS parameter estimates, maximum likelihood procedures are fundamental, but data screening and filtering can simplify estimation. Tests and estimators are clearly sensitive not only to the MAUP but also to the specification of the spatial interaction structure represented by the spatial weight matrix.

There have been substantial advances in the analysis of area data in the past decade, illustrating that ignoring space by involving an inappropriate model specification will give wrong answers, and wrongly interpreting the parameters of an appropriate model is equally likely to mislead. An appropriate model in many circumstances turns out to be the spatial Durbin model (see LeSage and Fischer, 2008; LeSage and Pace, 2009) that is characterized by both a spatially lagged dependent variable and spatially lagged explanatory variables. The presence of lagged variables leads to nuances with respect to the interpretation of the effects of variables, since spillovers cause both direct and indirect effects that need to be accounted for.

Conclusions

The field of spatial data analysis has been growing in many directions in recent years. Four key areas for future growth are especially important to note. First, static (cross-sectional in time) spatial data analysis is restricted to analyzing and modeling some process at some specific point in time. A series of spatial analyses over time can shed light on change, but in other respects remains limited. The understanding that has been gained by the progress made in spatial statistics and spatial econometrics forms an essential element in the emergence of spatiotemporal data analysis.

A second key area relates to spatial data mining, the process of discovering interesting and potentially useful patterns in spatial databases (Miller and Han, 2009). Spatial data mining shares some of the objectives of ESDA, but is concerned with the development of automated procedures that can be applied to very large spatial databases for the purpose of detecting spatial clusters, spatial outliers and co-location and relationship patterns among different classes of point, line, and polygon (area) objects.

Third, neural networks have an important role to play as universal approximators in areas such as regression analysis, classification, and spatial interaction in application domains where solutions require knowledge that is difficult to specify a priori, but for which there are sufficient observations (see Fischer, 2009; Gopal and Fischer, 1996). For neural networks to find a place in spatial data analysis, they need to overcome some current limitations, mainly due to the relative absence of established procedures for model identification, comparable to those for spatial econometric modeling techniques. In particular, providing tests specifically designed to test the adequacy of neural network models is a research issue on its own right. Another important avenue for further research is the incorporation of spatial dependency in the network representation, which has received less attention in the past than it deserves.

Finally, as spatially referenced data sets become more prevalent in scientific applications, the desire for full inference and accurate assessment of model uncertainty has become increasingly important. Bayesian hierarchical models may be seen as a means for capturing different sources of uncertainty accurately, but such models present several computational challenges (LeSage et al., 2009). The special issue of *Computational Statistics and Data Analysis* – 'Spatial statistics: methods, models & computation' – has a number of articles that illustrate computationally feasible hierarchical models for analyzing challenging spatial data sets.

Abstract

Spatial association means connectedness or relationship between and among variables over space (the Earth's surface). A single variable may be *spatially autocorrelated*; that is, values of the variable are somehow connected or related spatially. Many variables may be associated with one another at one or more sites. If there is spatial interaction, there is also spatial association. Maps can depict spatial association. A mathematical shorthand technique can be used to represent, in general, measures of spatial association. Scientists test or theorize about variables to determine whether spatial association, either observed or expected, actually can be confirmed. Statistical procedures that have been developed for identifying and measuring the existence of spatial association are outlined.

Introduction

Spatial association can characterize a single variable or many variables simultaneously. A single variable may be *spatially autocorrelated*; that is, values of the variable are somehow connected or related spatially (*see* Spatial Autocorrelation). Many variables – say, environmental variables such as air quality, water quality, certain species location, and human activities – may be associated one with another at one or more sites. In addition, spatial association and *spatial interaction* are related (*see* Spatial Interaction). If there is spatial interaction, for example, the movement of commuters to workplaces, there is also spatial association since home places are spatially connected to workplaces.

The scientist interested in the study of spatial association is motivated by the need to understand the spatial relationships between variables at specific sites or how variables of interest are spread across the Earth's surface. Many disciplines are particularly concerned with the study of spatial association. Among them are geography, regional science, ecology, epidemiology, regional and urban economics, geology, hydrology, and geomorphology. Since this is a broad and popular interest area, many methods and techniques of analysis have been created to confirm notions of spatial association between and among variables (Fischer and Getis, 2010). Scientists test or theorize about variables to determine whether spatial association, either observed or expected, actually can be confirmed. As a result of this interest, statistical procedures have been developed for identifying and measuring the existence of spatial association. After a short discussion of maps depicting spatial association, the remainder of this article will outline the characteristics of measurement procedures.

Maps Showing Spatial Association

Maps depicting spatial association fall into several categories: *in situ*, flows, time series, distance decay, and residuals. *In situ* maps reveal by means of overlays the possible association of two or more variables in a region (see Figure 1). Flow maps show the interaction between sites (see Figure 2). Time series usually are shown as a series of map views over time (days, years, etc.). These represent spatial relationships as they evolve or change over time (see Figure 3(a–c)). Distance-decay maps emphasize Tobler's first law of geography that "everything is related to everything else, [but] near things are more related than distant things." A distance-decay map might show that the effect of an earthquake declines with distance from its epicenter or that the influence of a retail store declines with distance from its site (see Figure 4). Residual maps show the remaining 'unexplained' variation after a model has been used to statistically explain a relationship between two or more variables

Figure 1 The study area represented by the black square indicates that there may be an *in situ* relationship among the three variables shown by different shading.

Figure 2 The width of the arrows indicates the magnitude of the interaction.

Figure 3 Over time {(a), (b), (c)}, there is an increase in the number of events at the same time as spacing between events is reduced.

Figure 4 On the plane, as distance increases from A to B the effect on A of the variable indicated by the vertical triangle declines.

Figure 5 In standard deviational units, the map shows residuals from a regression model. It remains to be determined whether or not there is a spatially statistically significant association among the residuals.

(see Figure 5). The unexplained spatial variation represents that part of whatever total variation exists in a mathematical model that is not accounted for by the variables included in the model. Residual maps help researchers identify new variables that might belong in a more complete model, such as a transportation cost, a regional effect, or a previously unidentified physical or human anomaly.

Spatial Association in Matrix Terms

To answer scientific questions about spatial association, one can reduce the complexities of what one sees on a map to a mathematically manipulable set of numbers (Hubert et al., 1981; Getis, 1991). The following simple cross-product formula represents spatial association:

$$\Gamma = \sum_{i}^{n} \sum_{j}^{n} w_{ij} y_{ij} \qquad [1]$$

Γ is the measure of spatial association, and the w_{ij} are contained in a matrix, **W**, of values that represent the relationship of each location of interest to all other sites (see Figure 6(a) and (b)). Figure 6(a) is a hypothetical map of 10 regions. The numbers in parentheses represent the value that a hypothetical variable, Y, takes in each of the regions. Suppose, it is decided that regions that are contiguous to one another are associated. The **W** matrix (Figure 6(b)) indicates the spatial relationship of each region to every other. For Figure 6(b), the convention is adopted of placing a one in the matrix if a link (contiguity) exists and zero otherwise. The **Y** matrix (see Figure 6(c))

J	0	0	0	0	0	**1**	0	0	**5**	0

$\Gamma = 66$

Figure 7 The value of Γ is made up of the sum of numbers shown in bold.

contains numbers that are the absolute difference between values for all combinations of the regions. For example, the absolute difference between values in regions C and E is shown as an element of the **Y** matrix in row C and column E, that is, $|6 - 7| = 1$.

The two matrixes, when summed as a cross-product as shown in eqn [1] (see **Figure 7**), give the value of Γ. If the values in the **Y** matrix are small for those same rows and columns that correspond to the $w_{ij} = 1$ values in the **W** matrix, the value of Γ will be small. For the example shown, Γ equals 66, an average of 2.2 for each of the 30 links between contiguous regions. If the number one appeared in all the **W** cells, the total Γ would have been 300 or a mean of 3.3 for each of the hypothetical 90 links. The implication here is that the contiguous neighbors that characterize **W** gives a smaller gamma value than one might expect if the values w_{ij} were randomly placed in the 10 regions. Γ indicates that there may be a spatial association among the Y values. We use the term 'may be' to indicate that we have not yet used a statistical test to confirm that Y is in fact a spatially associated variable.

The W Matrix

In the preceding paragraph, we outlined a simple form of a **W** matrix, one that was constructed based on contiguous spatial relationships between regions. The **W** matrix embodies our preconceived or derived understanding of spatial relationships. If we believe, or if theory tells us, that a particular spatial relationship is distance dependent, then the **W** matrix should reflect that supposition. For example, if it is assumed that a spatial relationship declines in strength as distance increases from any given site, then the **W** matrix will show that nearby areas are weighted more highly than sites that are far from one another. Various distance-decay formulations theorized or derived for such phenomena as travel behavior, economic interaction, or disease transmission would require the elements within the **W** matrix to reflect these effects. Thus, a typical **W** matrix might contain elements of the form $w_{ij} = 1/d_{ij}^{\alpha}$ (α greater than one). Thus, short distance relationships would be weighted more heavily than the long distances.

The Y Matrix

The nonspatial matrix, **Y**, gives us a view of how variables whose elements are georeferenced, that is, values of the variable are indexed at certain sites, *might* be associated with one another. The elements of the **Y** matrix, y_{ij}, represent the interaction of values of **Y**. Values can interact in a number of ways: addition, subtraction, multiplication, division, or combinations of these. An important type of interaction is that of covariance, that is, a value at one site may vary from the mean of all sites (the variation) and this difference is multiplied by the variation at another site. Taken over all sites, the *covariation* is

$$\sum_{i}^{n} \sum_{j}^{n} (y_i - \overline{y})(y_j - \overline{y})$$

and the *covariance* is this sum divided by the sample size, n.

Γ

When the matrix **W** and the matrix **Y** are similarly structured, one can conclude that **Y** values interact very much as the individual regions are spatially associated. Thus, Γ reveals the spatial association in the **Y** variable. In a previous example, we purposely created a **W** matrix that represented a relationship between contiguous regions. The fact that the values of the **Y** variable tend to be similar to one another when regions are contiguous allows us to conclude that the two matrices are similarly structured.

In the literature on spatial association, much attention has been given to the structure of **W** and **Y**. Each, in a sense, represents a related area of research. Those concerned with the **W** matrix have devised ever-increasingly complex representations of spatial relations among spatial units. From the simple contiguity structure presented earlier, empiricists and theorists have constructed **W** matrixes that represent supposed migration distances, disease transmission distances, assumed hierarchical spatial relations, political boundary effects, psychological distances, barriers to communication effects, economic effects of distance, social distances, and so on. In experimental work, the matrix **W** also has been used to represent concentric bands measured from various spatial foci or as representative of cumulative distances. These latter matrixes help researchers to identify 'critical' distances, that is, distances at which association reaches some peak.

Research on the structure of the **Y** matrix usually is a response to a particular type of possible spatial association. For example, the researcher may wonder whether the association is that of positive covariance. **Y** is structured in such a way that statistical tests can be carried out on the research hypothesis that statistically significant spatial association exists. Several of these formulations are given in the following section. Each is an alternative method of identifying spatial association.

Spatial Association as Covariance

Typical formula:

$$\sum_{i}^{n} \sum_{j}^{n} w_{ij}(y_i - \overline{y})(y_j - \overline{y}) \Big/ \sum_{i}^{n} \sum_{j}^{n} w_{ij}(y_i - \overline{y})^2, \quad i \neq j \qquad [2]$$

This is the well-known *Moran's I statistic*, explicated by Cliff and Ord (1981), and used widely as a measure of spatial

association for spatial residuals from regression analysis. When the data used for testing purposes are georeferenced, the basic form of the linear regression model requires that the error term be spatially distributed randomly. Moran's I is used as a test for the randomness of residuals from regression. The elements of the **W** matrix are represented as w_{ij}. The **Y** matrix is the covariance and the remainder of the equation is a scaling device used to give the statistic useful testing properties.

Spatial Association as Difference

Formulas:

$$\gamma(h) = \sum_{i}^{n-h} \sum_{j=1+h}^{n} w_{ij}(y_i - \bar{y})^2 / 2n(h) \qquad [3]$$

$$c = n - 1 \sum_{i}^{n} \sum_{j}^{n} w_{ij}(y_i - y_j)^2 / 2 \sum_{i}^{n} \sum_{j}^{n} w_{ij}(y_i - \bar{y})^2, \quad i \neq j \qquad [4]$$

The better known of these formulas is the first, called the *semivariance* or *variogram*. Widely used among geoscientists, this measure helps to identify the decline in spatial association as distance (h) increases away from the sites in question. It is the backbone for the large research area that yields continuous map surfaces common in studies of meteorology, geography, and geology (Cressie, 1993). **W** is again represented by w_{ij}. **Y** is made up of $(y_i - y_j)^2$ and the remainder of the equation is used to scale the semivariance in terms of the variance. Equation [4] is known as Geary's c.

Spatial Association as Clusters

Formula:

$$k(d) = \left[A \sum_{i}^{n} \sum_{j}^{n} w_{ij}(d) / \pi n(n-1) \right]^{1/2} \qquad [5]$$

This measure, called the *K-function*, helps to identify *spatial clustering* (Ripley, 1981) within the region A. It is used primarily in ecological and epidemiological studies (Diggle, 1983). The **W** matrix is made up of the w_{ij} elements, represented as ones, up to an arbitrary distance d. The **Y** matrix is invisible but is assumed to have each element equal to one. In practice, K values are found for a series of distances (Aldstadt, 2010). Tests usually are carried out by simulating alternative patterns of points (*see* Spatial Pattern, Analysis of).

Focused Spatial Association

Formula:

$$G_i^*(d) = \sum_{j}^{n} w_{ij}(d) y_j / \sum_{j}^{n} y_j \qquad [6]$$

For each type of measure shown in eqn [6], there is a counterpart (usually with some variation) that allows one to determine whether or not spatial association exists within the proximal region surrounding a single georeferenced point. A popular measure of this type is the *Getis–Ord statistic*, $G_i^*(d)$, which for the **Y** matrix each georeferenced point i is weighted (Getis and Ord, 1992). As distance increases from the site in question, values of G_i^* increase if clustering is in evidence; otherwise, they decrease. Anselin's *Local Indicators of Spatial Association* or *LISA* statistics are designed for focusing Moran's and Geary's statistics (Anselin, 1995).

The focused measures are based on comparisons between local conditions and regional conditions. If local circumstances indicate greater or lesser association than in the region as a whole, tests on statistically significant spatial clusters of high or low y values are in order. The O statistic of Ord and Getis (2001) is designed as a test of local spatial association in the presence of regional spatial association. The study of spatial clustering can be carried further to measures of associated variance within clusters themselves (Ord and Getis, 2012).

Spatial Association as Interaction

The basic formula:

$$T_{ij} = y_i y_j / w_{ij}^{-\beta} \qquad [7]$$

There are a number of interaction models; eqn [7] is the simplest. These widely used models enable transportation and economic researchers to estimate the flow of automobiles, aircraft, migrants, goods and services, and so on, between places (Haynes and Fotheringham, 1984). The **W** matrix usually represents a distance-decay function, while **Y** is usually a multiplicative interaction matrix.

All of these models have the Γ form. All can be used to test hypotheses about or to measure the extent of spatial association. Summaries on the measurement of spatial association can be found in Getis (1966, 1999), Bailey and Gatrell (1995) and Fischer and Getis (2010).

Spatial Autocorrelation

Robert Haining, University of Cambridge, Cambridge, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Spatial autocorrelation is used to describe a particular form of spatial variation found in geographical data. Its presence is often indicative of something of interest in mapped data that requires explanation; may be used to tackle map interpolation problems; may raise statistical inferential problems because data are no longer independent. We discuss how spatial autocorrelation is measured and its presence is tested for; implications for spatial sampling, exploratory spatial data analysis, map interpolation, and confirmatory analysis including regression modeling.

Spatial autocorrelation, one of the 'special' properties of spatial data (Haining, 2009), is the term used to describe the presence of a particular form of spatial variation in a variable that is observed and measured at different locations across a geographical area. Spatially referenced variables may assume values (1) at any point on a continuous surface (such as land use at a point in time or annual precipitation levels across a region); or (2) at a set of discrete sites at fixed locations within a region (such as prices for the same commodity reported at the same time at a set of geographically scattered retail outlets); or (3) across a set of areas that subdivide a region (such as the count or proportion of households currently receiving one or more welfare benefits or who have been victims of burglary in the last 12 months across a set of Census tracts that partition an urban region). The term 'spatial autocorrelation' is highly suggestive of its meaning: 'auto' as in 'self'; 'correlation' as in the statistical use of that term to measure a 'relationship' – hence a measure of the relationship between the value of a variable at a location and the same variable but at another location separated by some specified distance (or, in the case of type (3) variables, some measure of 'lag' separation between areas). Positive spatial autocorrelation is the tendency for sites or areas separated by a specified distance or 'lag' to have similar values of the variable (i.e., both values are high or both are low). Negative spatial autocorrelation is the tendency for the values to be dissimilar (if one value tends to be high, the other tends to be low and vice versa).

These terms are often used with specific reference to values for areas or point sites that are close together in space. If values, recorded at nearby points or areas across a map tend to have similar values, it is often said that the map displays positive spatial autocorrelation; if they are dissimilar we say that the map displays negative spatial autocorrelation. Although not common, negative spatial autocorrelation can arise naturally in cases (2) and (3). (For example, in the case of type (3) variables, think of a chess board where the squares are the areas and hence the units of observation. The juxtaposition of black and white squares indicates negative spatial autocorrelation at the scale of the squares.) By contrast, negative spatial autocorrelation is impossible to imagine in the case of the continuous type of variable mentioned earlier (in (1)) as the spatial distance between any two sample points converges toward zero.

The presence of spatial autocorrelation in map data is often taken as indicative of something of interest in the map (at the distance or 'lag' scale at which it is identified) that calls for further investigation in order to understand the reasons behind the observed spatial autocorrelation (Cliff and Ord, 1981). If geographic phenomena display spatial autocorrelation at some scale, then this may provide the starting point for theorizing about the spatial outcomes of processes that may have their roots in, for example, economic or social science theory.

If spatial data display spatial autocorrelation, this has important implications for the application of statistical methods to such data. The term spatial autocorrelation (or some similar concept) arises in several different data analysis contexts. For example, it arises in the fields of spatial statistics (Ripley, 1981; Cressie, 1991), spatial econometrics (Anselin, 1988), and geostatistics (Cressie, 1991; Isaaks and Srivastava, 1989). If there is spatial autocorrelation in a data set, data values are not independent and each value provides some information on the values of the same variable at nearby sites or adjacent areas. This implies that within the spatial data set there is information redundancy (since data values are not independent) and for the purposes of hypothesis testing the size of the sample is not the same as the number of independent observations of the process. It is with the recognition of this property that statistical methods for analyzing spatial data part company with the methods of traditional statistics (where any sample is assumed to comprise a set of independent observations), sharing ground instead with the sorts of methods used to analyze time series data (which typically displays 'temporal autocorrelation').

The following sections will describe how spatial autocorrelation arises; how it is measured and its presence tested for; and the implications of spatial autocorrelation for spatial sampling, exploratory spatial data analysis, map interpolation, and confirmatory analysis including regression modeling. For an overview of current issues as well as detail on the history of research into spatial autocorrelation in geography, see Griffith (2009).

How Does Spatial Autocorrelation Arise?

Spatial autocorrelation can be the outcome of a deterministic process or a stochastic (random) process. In the case of

a deterministic process, there is conceptually only one set of values (those that are observed), and it is the arrangement of these values across the region that are defined as spatially autocorrelated or not. In the case of type (2) and (3) data, the reference framework for deciding whether such a distribution of values is autocorrelated is the geographic distribution of values that would have been obtained, had those same values been allocated randomly to the points or areas in the region. In the case of a stochastic process, the observed values are but one set of realized values from an infinite set of possible realizations (a 'superpopulation') that are generated by a two-dimensional probability model. The variable may display spatial autocorrelation because it is a realization of a model where the random variables are spatially dependent. A conceptually simple example of such a model is the following, which is called the simultaneous (spatial) autoregressive model (Cliff and Ord, 1981). Let,

$$y(i) = \rho \sum_j w_{i,j} y(j) + e(i) \qquad [1]$$

where $y(i)$ is the observed value of the variable Y for area i (so this is a type (3) variable), and ρ is a parameter. $w_{i,j}$ is nonzero if area j ($j \neq i$) is a neighbor of area i (for example, area j shares a common boundary with area i; that is, area j is said to be at 'lag order 1' from area i) and is zero otherwise, and $w_{i,i} = 0$. The set, $\{e(i)\}$ is independent and identically distributed (iid) drawn from a normal distribution with mean zero and variance σ^2 (iid $N(0,\sigma^2)$). It can be shown that if $\rho > 0$, then Y will be positively spatially autocorrelated (and hence any map of realized values) because Y at i is a function of Y in the neighboring areas. For other examples of these types of spatial models, see Besag (1974, 1975) and for reviews, see Haining (2003), Cressie (1991), and Richardson (1992). There are other generators for spatially dependent variables, and such models may derive from models that incorporate both space and time into their specification (Berliner). In the context of a stochastic model, the term spatial autocorrelation has a closely proscribed meaning and is associated with the second-order moment (correlation) properties of the random variable.

When thinking about real processes (as opposed to purely mathematical models), then spatial autocorrelation in a variable can arise in a number of different ways. Here are some examples:

1. Many geographic variables display spatial continuity (temperature can be recorded everywhere and generally varies smoothly) in some cases referring to 'space-filling' objects (e.g., patches of forest, farmland, water bodies, etc.). If the spatial framework used to record the variable is at a smaller scale than the scale at which the variable varies across the region, then values in adjacent areas of the spatial framework will tend to be similar. Remote sensing provides an illustration of this point. If land use remains the same over large tracts of land, but a grid of small pixels is used to record land use, then neighboring pixels will tend to record the same value of the variable. The pixel values are (positively) spatially autocorrelated, and the smaller the pixels used to record values the more slowly will spatial autocorrelation decay with increasing lag (pixel step) distance.
2. Even if the scale of the spatial framework used for recording data values is the same as the scale at which the phenomena varies across the landscape, measurement error can introduce spatial autocorrelation. This can occur with certain types of surveys where recorders are given blocks to survey so that any operator-specific biases in the recording process will be similar within blocks and may therefore induce a form of spatial autocorrelation in the errors (Milne, 1959). Spatial autocorrelation in errors also arises with remotely sensed data due to the nature of the recording device on the satellite. Due to light scattering, what is recorded by the sensor in one pixel, which supposedly refers to one parcel of land on the ground, is actually a function of terrain characteristics in neighboring parcels (Foster, 1980).
3. Variable values may show spatial autocorrelation because they depend on an underlying process in which spatial relationships affect the way the process unfolds. There are a number of examples. Diffusion processes are processes where some attribute, like an infectious disease, spreads through a fixed population and the probability of a new individual becoming infected depends on spatial proximity to an already infected individual (Cliff and Ord, 1981). Spillover processes are processes where the attribute at some location is a function not only of conditions at that location but also of conditions in neighboring areas, for example, house prices as a function of local neighborhood conditions (Anas and Eum, 1984), or city income levels as a function of income levels in neighboring cities and rural areas arising because of consumer expenditure patterns (Haining, 1987). Interaction processes are where actions at one location influence actions at another location, such as price setting at one retail outlet influencing the prices set at other competitor sites (Haining, 1984). Dispersal processes are where individuals themselves disperse (like seeds around a parent plant or new settlers colonizing a region) so that population counts are autocorrelated (Cliff and Ord, 1981). In all these cases, at any point in time or when the process reaches some steady state, then the variable may show evidence of spatial autocorrelation.
4. The measured variable may not itself be the outcome of any of the foregoing situations but may be causally linked to another variable that is. In this case, the spatial structure of the dependent variable inherits the spatial structure of the independent variable to which it is related. Spatial autocorrelation in a variable may also arise because of spatial autocorrelation in underlying parameters. The incidence of a noninfectious disease like a respiratory condition may be autocorrelated because the relative risk of the disease (which is a parameter and is itself a function of environmental characteristics such as air quality) is spatially autocorrelated.
5. Spatial autocorrelation can be a property of a derived set of values such as the residuals from a regression model. In this case, spatial autocorrelation may have arisen because the regression model failed to include an important covariate that had a spatially autocorrelated structure. The spatial structure of the omitted independent variable is then inherited by the regression residuals.

For further discussion, see, for example, Fortin and Dale (2009).

Measuring and Testing for Spatial Autocorrelation

Autocorrelation Tests

There are several statistics for measuring and testing spatial autocorrelation. In the case of nominal data, the join-count test developed by Krishna Iyer (1949) may be used. The statistic is based on counting the number of joins of a particular color or colors on a map. Suppose each area is colored either black (B) or white (W). The join-count test is based on counting the number of BB, WW, or BW adjacencies on the map. If a map is positively spatially autocorrelated, then the number of BB and WW joins should be 'large' and the number of BW joins 'small.' If a map is negatively spatially autocorrelated, then the number of BW joins should be 'large' and the number of BB and WW joins 'small' (Haining, 2003). The terms 'large' and 'small' are determined with reference to the sampling distributions of these counts that would be expected if the black and white colors were allocated at random across the areas (Dacey, 1965).

In the case of ordinal- and interval-level data, the two tests most commonly used are the Geary test and the Moran test (Geary, 1954; Moran, 1948). The Geary test is based on differences between the values of adjacent areas: $(y(i) - y(j))^2$, where $y(i)$ and $y(j)$ denote the values observed in areas i and j, respectively. If areas i and j are adjacent and if the map is positively autocorrelated, then $(y(i) - y(j))^2$ should be 'small.' The Geary statistic is based on summing these squared differences across the map:

$$\sum_i \sum_j \delta_{i,j}(y(i) - y(j))^2 \qquad [2]$$

where $\delta_{i,j}$ is 1 if areas i and j are adjacent neighbors and zero otherwise ($\delta_{i,i} = 0$). The statistic, [2], will be 'small' in the case of positive spatial autocorrelation relative to the case of a random distribution of values. On the other hand, [2] will be 'large' in the case of negative spatial autocorrelation.

The Moran coefficient is based on cross products for adjacent areas:

$$\sum_i \sum_j \delta_{i,j}(y(i) - \bar{y})(y(j) - \bar{y}) \qquad [3]$$

where $\bar{y}$ is the mean of the observations on Y. In the case of a positively autocorrelated map pattern, [3] will be positive since usually both terms in the cross product will be positive or negative. In the case of a negatively autocorrelated map pattern, the terms will be negative, since if one of the terms is positive the other will usually be negative.

These statistics are appropriate to regular lattices but less appropriate for situations where the areal framework is irregular. Both [2] and [3] are invariant under certain transformations of the areal system but for any given area i some adjacencies are likely to be more important than others and should arguably therefore have greater weight in the calculation of any spatial autocorrelation statistic. In this case, the binary weight ($\delta_{i,j}$) is replaced by the more general weight ($w_{i,j}$). The weights may be chosen to reflect the topology of the areas or some hypothesis about the degree of contact between areas (Cliff and Ord, 1981). For example, $w_{i,j}$ can be defined to reflect the length of the shared common boundary between the two areas i and j, or the distance between the geographic centers of the two areas, or to reflect some measure of the intensity of interaction between the two areas in terms of, say, traffic or trade flow. For an extended discussion of these issues, see Dubin (2009).

The inference theories for the Geary and Moran statistics have been developed under two different conceptualizations of the null hypothesis of randomness or no spatial autocorrelation. In one case (the randomization hypothesis), the sampling distributions of the statistics are obtained assuming that the observed values are distributed at random across the region. In the other case (the normality assumption), the distributions of the statistics are obtained assuming that the observed values are independent drawings from a normal probability distribution with the same mean and variance for each area. The assumption of equal variance is a strong assumption and often questioned in the case of irregular areal partitions where population counts vary substantially between areas and where the population count appears in the denominator of the variable (Waldhor, 1996). For further discussion of inference issues for statistics from geographical data, see Brunsdon (2009).

There are other, simpler techniques for exploring spatial autocorrelation that can be useful (Haining, 2003). Simply mapping the variable can be informative as can graphing the scatterplot of paired data values $\{y(i), W^*y(i)\}$. $y(i)$ is the value observed in area i and $W^*y(i)$ is the value in the ith position of the matrix product of W^* with y. W^* is the matrix of general weights $\{w_{i,j}\}$ where each row has been standardized to sum to 1. So $W^*y(i)$ is a weighted average of the local values of y around i. If there is positive spatial autocorrelation present, the scatterplot will have a distribution of points sloping upward from the bottom left of the graph. If there is negative spatial autocorrelation, the scatterplot will have a distribution of points sloping downward from the top left of the graph. If the distribution of values is random, the scatterplot will have no discernable trend. Cressie (1984) describes other graphical methods for exploring the spatial structure.

Spatial Correlograms and Semivariograms

The tests for spatial autocorrelation described above can be implemented at any number of spatial scales. That is, the neighbors of any area i need not be restricted to the adjacent neighbors but can be extended to include more remote neighbors. It may be informative to examine spatial structure at a range of distances simultaneously. Spatial correlograms and semivariograms are plots of spatial structure at different distances. The correlogram at distance g has similarities with the Moran statistic. It is based on the expression:

$$\sum_i \sum_j w_{i,j}(g)(y(i) - \bar{y})(y(j) - \bar{y})$$

where $w_{i,j}(g)$ identifies all areas (j) that are at a distance g from the area i. Distance g can be defined in terms of a distance metric or in terms of 'lag distance,' that is the shortest path on a graph that connects adjacent areas (Haining, 2003). The spatial correlogram plot (with $g = 1, 2, 3, \ldots, G$ on the horizontal axis of the plot) thus provides a description of how spatial autocorrelation varies with distance.

The empirical semivariogram has similarities with the Geary statistic as it is based on the expression:

$$\sum_i \sum_j w_{i,j}(g)(y(i) - y(j))^2$$

This, like the correlogram, provides a plot of spatial structure with distance thereby showing how spatial structure varies with distance (Isaaks and Srivastava, 1989). Both the correlogram and the semivariogram may be used to suggest models for spatial variation; for examples in human geography, see the special issue of *Geographical Analysis* edited by Kerry et al. (2010).

A Test for Local Autocorrelation

The statistics in the Autocorrelation Tests section are often referred to as 'global' or 'whole map' tests of spatial autocorrelation because they compute an average measure using all the paired observations on the variable that are separated by the specified distance. But spatial autocorrelation might be a property of just a subset of the data, or the spatial autocorrelation structure may be different on different parts of the map. There might be a local tendency for similar values to cluster together, but this may not be a 'general' or 'global' property of the data.

Local tests for spatial autocorrelation compute the probability of getting the observed collection of values in a subset of the region if all the data values had been distributed at random over the area. The local Moran statistic ($I(i)$) is based on (Anselin, 1995):

$$(y(i) - \bar{y}) \sum_j w_{i,j}(y(j) - \bar{y}) \quad i = 1, \ldots, n$$

where n is the number of areas so that there are as many statistics and hence tests as there are cases. A high positive value of $I(i)$ signals a local spatial clustering of similar values, whereas a high negative value signals a local spatial clustering of dissimilar values.

Spatial Autocorrelation and Spatial Data Analysis

The presence of spatial autocorrelation in a variable has implications for a number of different areas of data collection and data analysis. These include spatial sampling, map interpolation, exploratory spatial data analysis, and confirmatory analysis including modeling. Each of these areas is briefly discussed in turn.

Spatial Sampling

Spatial sampling is the process of collecting data according to some specified set of rules and then using the data to make inferences about the population from which the sample has been drawn. Consider the case where the purpose of sampling is to estimate the proportion of an area covered by a particular type of land use. In this case, we do not adopt a 'superpopulation' view of the problem but rather focus on the 'here and now' of the land use geography. A conventional estimator for the quantity is the sample mean:

$$\bar{y} = \frac{1}{n} \sum_i y(i)$$

where n is the size of the sample and $y(i)$ is 1 if sample site i is occupied by the particular land use, and zero otherwise. One sampling decision to be taken is whether to take a random sample, a stratified random sample, or some form of systematic sample. The spatial autocorrelation in the land use surface has an important influence on the relative efficiency of these three designs because, as noted above, the presence of spatial autocorrelation signals that data values recorded at one location carry information about data values at nearby locations. The stronger the spatial autocorrelation on the surface, the more important it is to select sample sites that minimize the duplication of information within the sample. Random sampling is the least efficient sample design because there is no guarantee that sample points will not be clustered in particular areas of the map and hence their attribute values strongly autocorrelated. (In addition random sampling may leave large unsampled areas). Stratified random sampling overcomes the worst features of random sampling by ensuring coverage, but sample sites can still be adjacent to one another on either side of a strata boundary. Systematic sampling ensures a minimum separation distance between sample sites (Dunn and Harrison, 1993).

Map Interpolation

A range of estimators have been constructed to estimate values at specified locations where no data have been collected. One of the more widely used methods, the kriging estimator, has the generic form:

$$\hat{y}(k) = \sum_j \lambda_{k,j} y(j)$$

where $\hat{y}(k)$ is the estimate at location k where currently no datum is available (Berliner). The values $\{y(j)\}$ are the sample data, and $\{\lambda_{k,j}\}$ are coefficients that are a function of the spatial autocorrelation both between locations k and j and among the sample values (Isaaks and Srivastava, 1989). In this case, the presence of spatial autocorrelation is used to construct estimates of missing or unobserved values; in addition, confidence intervals can be attached to the estimates. This confidence interval is a function of sample density in the vicinity of the site to be interpolated. Confidence intervals will be large if the site k is far from sample points for which information is available and small if there are sample data nearby.

Exploratory Spatial Data Analysis

Disease atlases are constructed to represent the geographic variability of a disease. Maps of standardized mortality ratios (SMRs), for example, display the geography of relative risk for a particular disease and may be used to provide an indication of where the disease risk might be highest – perhaps as a preliminary to exploring for particular risk factors. Maps constructed using small geographic areas suffer from a number of problems – the estimated ratios tend to be

unstable with extreme rates often associated with areas with the smallest populations. Bayes adjustment methods are often used to adjust such standardized ratios. These methods incorporate information from the rest of the map in order to reduce some of the random variation that is present in each area's SMR. A subset of these methods does not just use the SMRs from the rest of the map but places greatest weight on those estimates closest to the area to be adjusted. For this adjustment, spatial process models are used and incorporate assumptions about the spatial autocorrelation in the relative risks into the adjustment process (Mollie, 1996).

Other, simpler smoothing methods may also be employed to provide evidence on broad patterns in a spatial data set, for example, mean and median smoothers (Haining et al., 1998). These techniques all implicitly exploit some aspect of the concept of spatial autocorrelation – that places near to an area, i, provide information on the value at i.

Information Loss in Statistical Tests

Spatial autocorrelation can undermine the use of classical statistical techniques (based on the assumption of data independence). We consider one example. The correlation coefficient (r) is a common statistic for measuring the linear relationship between two variables (X and Y). The Pearson correlation coefficient varies between -1 and $+1$, with $+1$ signifying a perfect positive relationship between X and Y (as X increases, Y increases). The inference theory for the correlation coefficient is based on:

$$(n-2)^{1/2}\,|\widehat{r}|\,\left(1-\widehat{r}^2\right)^{-1/2} \qquad [4]$$

where n is the sample size and $\widehat{r}$ is the estimated correlation coefficient. Under the null hypothesis that the correlation in the population is zero, [4] is t distributed with $(n-2)$ degrees of freedom. However, the amount of statistical information carried by the n observations when the data are (positively) spatially autocorrelated is less than would be the case were the n observations to be independent. In the terminology of Clifford and Richardson (1985), the 'effective sample size' is less than the actual sample size n so the degrees of freedom for the test is less than n. The solution to the problem is to compute this effective sample size (N') which is obtained from the spatial correlogram (see Section Map Interpolation). Then in [4], N' replaces n and the statistic is t distributed with $(N'-2)$ degrees of freedom. For other examples of the effect of spatial autocorrelation on classical statistical techniques, see Haining (2003).

Modeling Spatial Variation

The classical normal regression model is defined as:

$$y(i) = \sum_{k=0}^{K} \beta_k X_k(i) + e(i) \quad i = 1, \ldots, n$$

where y denotes the dependent variable, n is the number of sample sites, X_0 is a vector of 1s, and the X_k ($k = 1, \ldots, K$) denote the set of K independent variables. The model parameters to be estimated are denoted β_0, β_1, …, β_K where β_0 denotes the intercept parameter and the rest denote the regression parameters. The $e(1)$, …, $e(n)$ are iid $N(0,\sigma^2)$ errors. One of the assumptions of normal regression is that the errors are independent. If this assumption is violated (as, for example, when the errors are in fact spatially autocorrelated), tests of significance on the parameters of the independent variables are affected (the risk of a type I error is increased) and the usual goodness of fit measure is inflated. This assumption has to be tested using the regression residuals (which are estimates of the errors). In the case of spatial data, an adaptation of the Moran test is often used, although other tests are available (Anselin, 1988, 2009). If the null hypothesis of no spatial autocorrelation is rejected, then remedial action is needed to avoid misspecification error. One approach is to seek out other independent variables that, because they were originally (and wrongly) excluded and spatially autocorrelated, caused the residual autocorrelation. Other forms of model specification may also need to be considered which include interaction terms, diffusion process terms, or spillover terms (see Section Measuring and Testing for Spatial Autocorrelation). Thus a respecified regression model might include spatially lagged terms of the dependent variable, one or more of the independent variables or a spatial model imposed on the errors. (Examples of these and other models are described in Ord, 1975; Anselin, 1988, 2009; Haining, 2003; Cressie, 1991.) Residual spatial autocorrelation undermines other forms of regression analysis including Poisson regression used to model small area count data (e.g., numbers of cases of a disease by area). A solution to this problem may entail the use of a spatial random effects term in the specification of the Poisson mean (Griffith and Haining, 2006; Law et al., 2006). A common underlying thread here is the problem of 'information loss,' associated with spatial autocorrelation, discussed in the Information Loss in Statistical Tests Section.

Spatial Cognition

Daniel R Montello, University of California, Santa Barbara, CA, USA

Abstract

Spatial cognition concerns the study of knowledge and beliefs about spatial properties of objects and events in the world, and as such objects and events are represented in maps, language, and other symbol systems. Geographers study spatial cognition to address questions such as how spatial knowledge and beliefs are acquired and develop over time; the nature of spatial knowledge structures and processes; how people navigate and stay oriented in space; how people use language to communicate with each other about space; and how aspects of spatial knowledge and reasoning are similar or different among individuals or groups.

Spatial cognition concerns the study of knowledge and beliefs about spatial properties of individual objects and events, or collections of objects and events. Cognition is about knowledge: its acquisition, storage and retrieval, manipulation, and use by humans, nonhuman animals, and intelligent machines. Cognitive systems include sensation and perception, thinking, mental imagery, memory, learning, language, reasoning, and problem solving. Spatial properties include location, size, distance, direction, separation and connection, shape, pattern, movement trajectory, and more. These properties characterize the small and the large, but geographers focus on scales relevant to human activities on the earth's surface, such as temporary travel, migration, settlement, and economic activity. As such, geographers are mostly interested in the spaces of buildings, neighborhoods, parks, forests, mountain ranges, crop fields, cities, provinces, and countries. Geographers are also interested in the spaces of external symbolic representations of earth places and features, such as cartographic maps, language, and other geographic information displays. Spatial cognition plays a central role in many human activities and helps solve many human problems (Allen, 2007; Montello and Raubal, 2012), several of which geographers study. Cognition of and with spatiality is a fundamental component of human experience and is functional and relevant in many situations, both everyday and exceptional. The study of spatial cognition in geography sheds light on questions such as how spatial knowledge and beliefs are acquired and develop over time; the nature of spatial knowledge structures and processes; how people navigate and stay oriented in space; how people use language to communicate with each other about space and spatiality; and how aspects of spatial knowledge and reasoning are similar or different among individuals or groups. Among other issues, future research will concentrate on how understanding spatial cognition can improve the design and implementation of information technologies and on how technologies will change the cognition of space and place.

In humans, cognitive structures and processes are part of the mind, which emerges from a brain and nervous system inside of a human body that exists in a social and physical world. Within the last couple of decades, considerable advances have been made in understanding the brain bases for spatial cognition, including its neural and chemical underpinnings (Byrne et al., 2007; Maguire et al., 2000). Many of the advances in this area of research have resulted from new technologies, particularly functional magnetic resonance imaging, for scanning the ongoing real-time activities of the brains of healthy individuals engaged in cognitive acts, such as attempting to figure out where they are located in space. Spatial cognitive neuroscience continues, constituting some of the most important ongoing scientific research on spatial cognition today. Even geographers have started to explore these approaches to researching spatial cognition (Lobben et al., 2009). However, it is important to recognize that an increased understanding of the brain bases for spatial cognition does not eliminate the need to understand spatial cognition at functional, semantic, experiential, computational, environmental, and social levels.

The Geographic Study of Spatial Cognition

Geographers study spatial cognition for three reasons (Downs and Stea, 1973; Golledge, 1987). First and foremost, spatial cognition provides questions of geographic interest in their own right, given that cognition about space and place is an expression of human–environment or human–earth relations. Second, geographers have hoped that spatial cognition would improve their understanding of traditional phenomena of interest; for example, where people choose to shop should depend in part on their beliefs about distances and road connections. Finally, there has been an interest in improving the use and design of maps and other geographic information products which depend in part on human understanding of depicted spatial relations.

In addition to geographers and cartographers, researchers from many different disciplines study spatial cognition, including psychologists, linguists, biologists, computer scientists, architects and planners, anthropologists, and philosophers. Overviews of spatial cognition from various disciplinary perspectives, including geography and cartography, can be found in Allen (2004), Kitchin and Blades (2002), Lloyd (1997), McNamara et al. (2008), and Waller and Nadel (2012). While overlapping and interacting with these disciplines, the geographer's interest in spatial cognition is distinct in some ways. Geographers are interested in the earth

as the home of humanity. Their concern is with the cognition of humans, not the cognition of barn swallows or undersea robots. Geographers focus on spatial scales relevant to human activities on the earth's surface, such as daily travel, migration, settlement, and economic activities; a geographer wants to understand human conceptualizations of the layout of a city or a region, not of an atom, a desktop, or the solar system. Finally, the geographer ultimately desires to describe, predict, and explain external human–environment relationships, and focuses on internal mental and neuropsychological structures and processes only insofar as such internal structures and processes help in the understanding of external relationships.

History of Spatial Cognition in Geography

The notion that a subjective understanding of space partially mediates human relationships with an objective physical world is undoubtedly quite old. Within the modern discipline of geography, the study of spatial cognition first appeared with the work on geographic education early in the twentieth century. However, interest in spatial cognition flowered during the 1950s and 1960s. The subdiscipline of experimental cartography emerged with the insight that maps could be improved by understanding how humans perceive and think about information depicted in map symbols. In an attempt to explain human responses to floods and other natural hazards, the subdiscipline of environmental perception began to study people's subjective beliefs about the occurrence and consequences of hazard events. Most importantly for the study of spatial cognition, behavioral geographers began developing theories and models of the human reasoning and decision making involved in spatial behavior, for example, migration, vacationing, and trip scheduling. This approach gained insight from the work of Lynch (1960), a planner who argued that 'images' of cities guide people's behavior and experiences of those cities. All of these historical developments constituted a new focus on disaggregate or microscale approaches within human geography, approaches that focused on the geographic behavior of individuals as an accompaniment to traditional approaches that focused on human settlements and larger aggregations of people.

Topics in the Geographic Study of Spatial Cognition

The study of spatial cognition in geography sheds light on questions such as how spatial knowledge and beliefs are acquired and develop over time; the nature of spatial knowledge structures and processes; how people navigate and stay oriented in space; how people use language to communicate with each other about space; and how aspects of spatial knowledge and reasoning are similar or different among individuals or groups.

Acquisition and Development

Humans acquire spatial knowledge and beliefs directly as they move about the world via sensorimotor systems; they move their bodies in and through space, they see spatial properties and relations, they feel them with their hands, they hear them, and so on. People also acquire spatial knowledge indirectly via static and dynamic symbolic media such as maps and imagery, graphs, 3D models, animations, natural language, and virtual reality. Geographers are interested in how different media have consequences for the nature of acquired knowledge.

Spatial knowledge changes over time, through processes of learning and development. Changes in the child's spatial knowledge and reasoning (Newcombe and Huttenlocher, 2000) as well as changes an adult experiences while visiting a new place for the first time are of interest to geographers. Both physical maturation and experience influence development. A person's activity space – the set of paths, places, and regions traveled on a regular basis – is an important example of spatial experience that influences people's knowledge of space and place, no matter what their age is. Most people know the areas around their homes or work places most thoroughly, for example (as in the anchor-point theory of Couclelis et al., 1987).

A widely accepted model of spatial learning suggests that spatial knowledge of places develops in a sequence of three stages or elements (Siegel and White, 1975). First is landmark knowledge, based on the unique features or views that identify a place. Second is route knowledge, based on travel routines that connect ordered sequences of landmarks. The final element is survey knowledge, that is, quantitative knowledge of two-dimensional layouts that includes the simultaneous interrelations of locations; survey knowledge would support detouring and shortcutting. However, increasing evidence (Ishikawa and Montello, 2006) indicates that some people acquire survey knowledge surprisingly quickly, essentially as soon as they encounter a new place; at the same time, some people very slowly or never develop detailed or comprehensive survey knowledge of their surrounds.

Exposure to maps of places clearly advances the development of survey knowledge for most people. An interesting proposal by Uttal (2000) even suggests that we conceptualize earth-surface layouts as survey representations only because we are exposed so early and often to cartographic maps in our culture. Either way, geographers are interested in how people acquire spatial knowledge not only directly, but also indirectly, from maps, satellite imagery, globes, and other iconic symbol displays. Notably, people can learn spatial properties of very large or small spaces (continents, molecules) only via indirect sources such as maps, whereas in many other cases, people learn spatial properties via both direct and indirect sources (Thorndyke and Hayes-Roth, 1982). In other cases, people even acquire nonspatial knowledge by interpreting spatial displays that metaphorically represent nonspatial information (Skupin and Fabrikant, 2008).

Spatial Knowledge Structures and Processes

The metaphor of a cognitive map was coined by Tolman in a 1948 paper to refer to internally represented spatial models of the environment. The cognitive (or mental) map includes knowledge of landmarks, route connections, and distance

and direction relations; nonspatial attributes and emotional associations are stored as well (Downs and Stea, 1973). However, in many ways, the cognitive map is not like a cartographic 'map in the head' (Tversky, 2000). It is not a unitary integrated representation, but consists of stored discrete pieces including landmarks, route segments, and regions. The separate pieces are often partially linked or associated so as to represent hierarchies, such as the location of a place inside of a larger region (McNamara et al., 1989; Stevens and Coupe, 1978). Furthermore, spatial knowledge is not well modeled by metric geometries such as the Euclidean geometry of high school math. The ways in which spatial knowledge is internally represented in human minds lead to certain patterns of distortions in the way people answer spatial questions. For example, people often believe the distance from place A to B is different than from B to A. Turns are frequently adjusted in memory to be more like straight lines or right angles. At larger scales, most people have somewhat distorted ideas about the sizes and locations of continental land masses on the earth; for example, South America is thought to be due south of North America when it is actually rather far to the east as well. Friedman and Brown (2000) showed convincingly that people organize their understanding of spatial relations at global scales largely in terms of regions that simplify spatial content by exaggerating the similarity of latitudes of places within a region while exaggerating differences in latitudes of places between regions (Figure 1). Interestingly, these global regions in some cases correspond to countries or continents, and sometimes they do not.

Navigation and Orientation

Humans travel over the earth's surface to reach destinations. This typically requires planning and the ability to stay oriented while moving. Navigation is this coordinated and goal-directed travel through space. It can be understood to consist of two components, locomotion and wayfinding (Montello, 2005). Locomotion refers to guiding oneself through space in response to local sensorimotor information in the immediate surrounds, and includes such tasks as identifying surfaces of support, avoiding obstacles, and moving toward visible landmarks. Locomotion generally occurs without the need for an internal model or cognitive map of the environment. Wayfinding refers to the planning and decision making that allows one to reach a destination that is not in the immediate sensory field, and includes such tasks as choosing efficient routes, scheduling destination sequences, orientating to nonlocal features, and interpreting verbal route directions. Wayfinding tasks generally do require a cognitive or cartographic map of the environment. Various locomotion and wayfinding tasks vary greatly in their demand on attentional capacity. Following a familiar route is not very demanding on attention; finding one's way in a new city may be quite demanding.

Orientation is knowing "where you are," although the precision and comprehensiveness of this knowing varies greatly in different situations and for different people. Two fundamental processes are involved in orientation during navigation (Golledge, 1999). The first process is the recognition of external features or landmarks, also known as pilotage. In some cases,

Figure 1 Patterns of latitude estimates for world cities indicate regional organization and reasoning for spatial knowledge about world geography. Cities on the abscissa are ordered according to estimated latitudes in the western and eastern hemispheres. Reproduced from Friedman, Alinda, Brown, Norman R., 2000. Reasoning about geography. Journal of Experimental Psychology: General 129, 193–219.

the recognized landmark is the goal, but more commonly the landmark aids orientation by serving as a key to the knowledge of spatial relations stored in an internal cognitive or external cartographic map. The second process is dead reckoning, updating a sense of orientation by integrating information about movement speed, direction, and/or acceleration without reference to recognized features.

People also use symbolic media such as maps to navigate and stay oriented. Maps used for navigation show robust alignment effects, a common confusion when using navigation maps with the top of the map not being the direction in the surrounds that one is facing when looking at the map. Alignment effects results from the fact that spatial perception is orientation dependent; objects and pictures have a subjective top and bottom, and forwards and backwards, in the perceptual field and in memory. In the case of road or trail maps, many people turn the map to bring about alignment. Digital navigation systems typically turn this way automatically. Unfortunately, this option is not available with ubiquitous 'You-Are-Here' maps, which are surprisingly often mounted in the environment in a misaligned way with respect to the viewer's perspective. The resulting alignment effect is the fact that most people interpret misaligned maps more slowly, with greater error, and/or with dissatisfaction (Levine et al., 1984). While an annoyance in many situations, misaligned emergency maps placed in public buildings are potentially disastrous.

Spatial Communication via Language

Spatial information is often communicated verbally, in natural language such as English or Chinese. People give and receive verbal route directions, read spatial descriptions contained in stories, and increasingly interact with computer systems via verbal queries. There are at least two notable characteristics of the way language expresses spatial information (Bloom et al., 1996; Mark and Frank, 1991). One is that language expresses mostly nonquantitative or imprecise ('fuzzy') quantitative information about space. Statements about connections and approximate location are more important than precise statements. For example, people say "turn left at the gas station" rather than "turn 80° after you go 0.6 miles." Great precision is typically unnecessary or even confusing. A second characteristic is that various aspects of the context of communication are critical in interpreting spatial language. Context is provided by knowledge of who is speaking, where they are, physical features in the situation, the previous topic of conversation, and so on. "The bicycle is near the church" is generally understood differently from "France is near England."

Individual and Group Similarities and Differences

No two individuals know exactly the same things or reason in exactly the same way about space and place. Some people are better at tasks such as wayfinding, learning spatial layouts, or reading maps. In some cases, there may be different ways to think about such problems, all of which may be effective. In such cases, one might speak of stylistic differences in spatial cognition rather than ability differences. Geographers and others are interested in measuring and explaining such individual differences. Traditional psychometric paper-and-pencil tests of spatial abilities tend not to measure these differences very well (Allen et al., 1996).

Many factors may contribute to variations in spatial cognition: body size, age, education, expertise, sex, social status, language, culture, and more (Levinson, 2003; Liben et al., 1981). A first goal for geographic research is to measure and document ways these factors might covary with spatial cognition. Females and males appear to differ in some ways in their spatial abilities and styles, for example, but not in others (Montello et al., 1999). In addition to describing such covariations, geographers have the research goal of distinguishing their underlying causes. For example, the two sexes likely differ in their spatial cognition in part because of different travel experiences afforded them as children by their socialized roles. Explanations for such covariations are generally quite difficult to determine, however, as one cannot readily do randomized experiments on person characteristics such as age, sex, culture, and activity preferences.

Technologies and the Future of Spatial Cognition Research

As stated earlier in this article, future research will continue examining the interactions of new information technologies and spatial cognition. Understanding spatial cognition should improve technology, increasing its ease of use, its effectiveness, its profitability, and its equitable distribution in society. Relevant technologies include mapping and route direction sites on the Web, geographic information system (GIS), global positioning system (GPS)-enabled navigation systems in automobiles and on cell phones, the computer-simulated worlds known as virtual reality or virtual environments, and location-based systems and services more generally (Montello and Raubal, 2012). A host of spatial-cognition questions are inspired by efforts to improve the effectiveness and efficiency of information systems (Hirtle, 2011). How can complex spatial and thematic information be depicted to promote comprehension and effective decision making, whether through maps, graphs, verbal descriptions, or animations? Although spatial cognition researchers believe in the practical usefulness of their research (Allen, 2007), there are not many clear demonstrations yet of its widespread application.

Furthermore, information technologies are likely to change spatial cognition, and our experiences and behaviors in space and place. Researchers will ask how exposure to new spatial information technologies will alter human ways of perceiving and thinking about the world. Will the regular use of GPS-enabled navigation systems diminish people's ability to maintain orientation by using perceptual-motor and cognitive systems? Will this be offset by the great reductions in lost time and lost lives resulting from using new technologies? The potential for technologies to enhance education is considerable (Committee on Support for Thinking Spatially: The Incorporation of Geographic Information Science Across the K–12 Curriculum, the National Research Council, 2006), but does the drive to integrate spatial technologies like GIS into educational settings run a risk of replacing thinking rather than

enhancing it? Ongoing and future research will shed light on these questions and more.

Abstract

A fundamental question for developmental science is: how do young children represent the space around them. This question has been empirically approached from a number of angles. In this article, we describe some of these approaches and report on key findings regarding spatial cognition development in infants and young children. The specific areas covered here include developmental studies of spatial categorization in infants, spatial frames of reference available to infants and young children, geometric cue use by toddlers, and cultural variations in spatial thinking and spatial language.

Introduction

Spatial cognition involves the attainment, use, and adjustment of knowledge about spatial relationships and environments. The development of spatial cognition abilities is essential for a variety of skills essential for daily functioning (e.g., finding one's way around) and for higher-order processes (e.g., advanced mathematics). As such, an understanding of what young children understand about three-dimensional space and how this knowledge arises is of fundamental interest to developmental science.

Since space is universal to all organisms, one could hypothesize that knowledge of the metric properties of space should be innately available to infants. Alternatively, one could assume that space and all of the external world become represented as separate from the infant over time as a result of the infant's interaction with their world.

These questions have made the study of children's spatial representations an area of intense interest in the broader field of developmental science. In this article, we describe some of the major areas of study and key findings with respect to spatial cognition development in infants and young children. These areas include developmental studies of spatial categorization, spatial frames of reference, geometric cue use, and cultural variations.

Spatial Categorization in Infancy

'Spatial categorization' is a term that has been used to describe a variety of concepts. Here we focus on how the developing mind categorizes the relationships that are held between two objects. For example, adults often describe spatial relationships between objects as '*above/below*,' 'to the *right/left* of,' and '*inside/outside* of.' Developmental scientists have extensively studied the ability of preverbal infants to mentally classify such relationships.

Categorization of Simple Relationships

Beginning with the seminal work of Quinn (1994), the bulk of infant categorization studies have relied on experiments in which infants were habituated or familiarized with a particular spatial array and then were presented with a spatial array that differed from the original in some spatial dimension. In this series of experiments, Quinn (1994) habituated 3-month-old infants to a display where a dot was presented either above or below a horizontal line (see **Figure 1**). Following habituation, infants were found to recover interest when the dot had a new location in relation to the line (i.e., they looked longer at a dot above the line after habituating to the dot below the line). After conducting a series of controlled experiments to rule out explanations relating to encoding of the dot's actual position, it was concluded that infants can categorize and represent *above* and *below* relationships.

Recent research demonstrates that this ability varies across age depending on the particular spatial relationship under examination (Casasola, 2008). In fact, the earliest demonstration of spatial category is that of *left/right* relationships. Gava et al. (2009) found that under certain conditions even 3-day-old infants demonstrate discrimination between spatial configurations representing this relationship, suggesting that rudimentary spatial categorization is innate. Using a habituation paradigm, neonates were presented with various arrangements on a simple black and white display of moving or blinking dots on either side of a referent line. They found that infants were particularly sensitive to changes in the *left/right* relationship between two stimuli, rather than the absolute distance between the stimuli. It is worth noting that this very early ability is weak and highly constrained. The results were likely facilitated by the very simple testing

Figure 1

Table 1

conditions used. Yet employing very simple, somewhat ecologically limited stimuli may be a necessary trade-off when assessing spatial categorization in newborns with very poor visual capacities.

Categorization in the vertical plane is generally not demonstrated until at least 3 months of age (Newcombe, 2002). While the *above/below* relationship is arguably comparable in perceptual complexity to *left/right* relations, the ability to classify the former develops second. This difference in onset may stem from infants having greater early capacity for eye movements in across the horizontal rather than the vertical plane (Gava et al., 2009; Quinn et al., 1996).

Even beyond a growing ability to differentiate in the vertical plane, spatial categorization development continues through the first year of infancy. For example, categorization at 3–4 months remains dependent on the presence of a central referent line, as infants do not seem to be able to internally generate a perceptual midline (Quinn, 1994). Additionally, until 6–7 months of age, this type of spatial discrimination falters when infants are prompted to categorize the locations of even slightly complex shapes. Specifically, infants at 3 months will readily discriminate *above/below* relationships, provided that the object has a simple shape, but not when it is more complex.

Categorization of More Complex Relationships

From 6 months of age, infants demonstrate a rudimentary recognition of the spatial categories of *between* and *containment* (Casasola et al., 2003). However, abstraction of these spatial categories does not appear until about 10 and 14 months of age (Casasola and Cohen, 2002). It is thought that this difference is due to the requisite two landmarks that must be referenced in order to establish a *between* relationship. This ability develops later, and is perceptually more complex than making reference to a single landmark (e.g., *above/below spatial categorization*; Lew et al., 2000).

With respect to understanding the *containment* relationship, different types of experimental paradigms reveal varying levels of spatial understanding in infants. When infants are prompted to manually place an object into a container, infants first demonstrate competence at around 14 months of age. Between 15 and 30 months of age, a great improvement is seen in infants' understandings of specific containment principles. For example, Shutts et al. (2009) observed that across this time period, infants took an increasing amount of care when selecting an object to insert into an aperture of a given size and shape. Prior to this point, infants demonstrate little selectivity. It has been suggested that a developing ability in mental rotation is a primary driver of developmental ability in such tasks (Levine et al., 1999).

In order to complete this seemingly simple object-into-aperture activity, it is also necessary to be able to relate the positive shape of the object to the negative space of the hole. This idea is perhaps more complex than it initially appears, as even adults tend to represent the shape of the negative space differently to the shape of the positive space, even when they are complementary (Bertamini and Croucher, 2003).

Categorization of the spatial relationship of *containment* highlights some of the inherent complexity in mapping development onto a timeline. As with other areas of infant cognition, findings of categorization ability depend largely on the type of experimental paradigm employed. For example, Hespos and Baillargeon (2001) report the initial demonstration of containment relationships at 3 months of age using looking times, much earlier than the previously reported 14 months. These very young infants were found to look longer at containment relations that are not physically possible (e.g., a large peg fitting apparently into a small cylinder) compared to possible containment relationships. These findings arguably reflect the cognitive/perceptual building blocks for later *containment* categorization ability.

The understanding of *containment* and *support* as spatial categories coincides with a rise in the salience of spatial language. Specifically, the ability of an infant to discriminate between different types of *containment* or *support* may relate to the language with which they are familiar. For example, discrimination between tight- and loose-fit relationships for *containment* (such as a hand in a glove compared to an orange in a fruit bowl) and *support* (such as a building block pushed on to join another, compared to the blocks sitting on a table) is somewhat dependent on having the spatial vocabulary to describe (or at least reference) this difference (Casasola, 2008; see the last section of this article for reference to cultural variations arising from differences in the spatial language used).

Experience is another important factor in the formation of these more robust and complex categorical representations. Infants with more environmental experience are better able to determine if a space is occupied by one fused object or two separate objects (e.g., a cup and saucer; Needham, 2000). See **Table 1** for an overview of related studies.

Spatial Frames of Reference Used by Infants

So far, we have described the progression of infants' abilities in discriminating various relationships between objects. This kind of discriminative ability is necessary for certain successful object manipulations, but does not enable successful navigation through one's environment; nor does it enable proficient encoding and relocating of objects in one's environment. For this to be achieved, infants must possess and make use of a spatial 'frame of reference' (FoR).

With an effective FoR, one can represent their own position relative to their surroundings, as well as where items are located in relation to each other. There are a number of FoR types that are differentially suited to performing particular tasks. In the subsequent sections, we discuss commonly investigated FoRs with respect to infant spatial search ability.

Retinocentric versus Body-Centered FoRs

The *retinocentric* (eye-centered) FoR is a primitive spatial FoR and encodes locations as a series of eye movements. Such a FoR is best suited to learning repeating sequences of events while one is in a stationary position. For example, the locations of a bouncing ball could be encoded in this way: look up, then look down, then look up, etc. Retinocentric information can be extracted directly from sensory signals and involves comparing the point of interest with other points in the visual field in order to establish the object's position in space. Infant research on retinocentric frames has focused on how infants are able to progress to head or body-centric representations.

Initial evidence of a retinocentric limitation was demonstrated in a 'double-step' task with 3-month-old infants (Gilmore and Johnson, 1997). They found that after seeing two targets appear simultaneously (in the same horizontal plane) below a starting fixation point, infants were generally unable to compensate for their initial look to one first target when directing their gaze to the other target (see **Figure 2**). That is, they looked down to the first target correctly, but then looked down again to the second target when a lateral eye movement was necessary.

Kaufman et al. (2006) similarly found that 4-month-old infants who learned to follow a sequence of pictures appearing in opposite diagonal corners of a display showed retinocentric behavior when an unrelated, briefly presented stimulus appeared unexpectedly in the sequence. After the disruption, infants did not look back to a corner of the screen, but instead directed their gaze diagonally from the unrelated stimulus. Although complexity of the sequence and familiarity with the stimuli can influence retinocentric behavior, it is not until around 7 months of age that infants consistently account for intermediary eye movements and current eye position in sequence learning.

Figure 2

It is important to note that from the participant's perspective, a retinocentric FoR actually does work most of the time in these kinds of sequence learning tasks. Even if some of the stimuli are missed, generally when there is a consistent sequence, retinocentric-based eye movements will pay off with the child seeing the sought-after stimulus. But in tasks involving manual action or search, a retinocentric framework is almost entirely unsuitable. It is therefore not surprising that infants can and do employ body-centered representations under other circumstances.

Body-Centered versus Allocentric Representations

Early studies of infant FoRs were largely concerned with when infants are able to move from egocentric (or body-centered) representations to allocentric representations. Using a body-centered representation means that locations of objects are encoded with respect to the viewers' body – thus the effectiveness of this representational scheme fails once the viewer moves through space. In contrast, an allocentric representation entails representing locations with respect to an external framework (such as landmarks or other objects). To assess infants' ability to use these FoRs, researchers typically employ what can be called 'search-and-move' tasks. In such tasks, the infant initially searches (either manually or visually) for a hidden target in the experimental apparatus. Following this, the infant is moved around the apparatus to a new position (usually directly across from the starting position) whereupon he or she is prompted to search again for the desired target.

For example, Bremner (1978) used a version of this task where 8–9-month-old infants reached for a hidden toy in one of two hiding wells on a tabletop and were then passively moved around to the other side of the table where they were prompted to search again in a test trial. Generally, infants appeared to search 'egocentrically' or in a body-centered fashion. That is, if the toy was hidden in the hiding well on the left side of the table prior to the test trial, infants continued to reach to the left side following their passive movement in the test trial (although now the object is located on the right side from the infant's perspective). Similar findings were reported when infants were prompted to look through a right- or left-side window for a target rather than reach for a target (Acredolo, 1978).

While the results of this work have been interpreted as evidence for infants being limited to egocentric FoRs, subsequent work using variants of this task demonstrate greater representational flexibility even at very young ages. This research revealed numerous factors that can significantly reduce body-centered search in such tasks. These factors include the presence of salient, direct landmarks near the hiding position (e.g., Acredolo and Evans, 1980; Bremner, 1978), visible geometric cues (salient corners, walls, etc.) in the testing environment (Keating et al., 1986), and a familiarity with the testing environment (Acredolo, 1978).

More recent work suggests that the body-centered search tendencies of infants may stem not from a representational bottleneck, but rather from infants in these tasks not realizing that they were actually moved to a new position prior to the test trial. Kaufman and Needham (1999, 2011) have argued that because reaching for hidden objects is so challenging for young infants, they may be focusing on the process of reaching at the expense of attending to their passive movement around the room prior to the test trial. Using a series of visual habituation experiments, it was found that infants as young as 4.5 months appear to habituate not only to a body-centered view of an object, but also to its actual position in the room. Infants were found to dishabituate when examining the same object in a new position even if the object maintained its egocentric relationship to the child.

It seems likely then that the reason that self-produced locomotion (i.e., the onset of crawling) appears to trigger spatial competence (Lew et al., 2000; Bai and Bertenthal, 1992) is not that it allows new forms of representation. Rather, locomotion experience increases motivation and ability to track self-movement around the room. This is consistent with a number of research findings which show that increasing the complexity of infant motion decreases subsequent search performance (Kaufman and Needham, 2011; Landau and Spelke, 1988). See **Table 2** for an overview of related studies.

Discrimination between object-centred arrangements (looking time)
Able to orient to a target without the use of landmarks (Lew et al., 2000)
Notable increase in exploration of the environment

Table 3

Geometric Cue Use in Infants and Young Children

In the previous section, it was noted that a failure to reorient could be misinterpreted as a limitation in representation ability. In many studies, infants were tested in environments with very sparse geometric cues, which it turns out, are often crucial to accurate reorientation. When experiments include informative geometric cues, they tend to reveal that infants perform markedly better at search-and-move tasks.

Processing of Geometric Information in Young Infants

As environmental geometric cues help performance in search-and-move tasks, it seems apparent that young infants have an ability to discriminate cues that differ in their geometry. Indeed, a number of studies have demonstrated this. For example, Lourenco and Huttenlocher (2008) used a looking-time procedure to examine whether 4.5–6.5 month olds were able to differentiate among the corners of a two-dimensional isosceles triangle presented on a screen. They found that when the orientation of the triangle was less variable, infants could discriminate between all corners, while for highly variable orientations, only the unique corner could be distinguished from the others.

Similarly, Bremner et al. (2007) have found that infants as young as 4 months of age are sensitive to an object's geometry. In this study, 4- and 8-month-old infants were familiarized with a T-shaped object with an internal light illuminating one of the T's three ends. When the object was rotated, infants showed a preference to look at the shape when the light's position was constant within the T-shape, regardless of the light's egocentric relationship with the infant. In order for this to happen, it is argued, infants must have formed a representation of the object's geometry.

Geometric Cue Use in Reorientation by Toddlers

While geometric cue use has been evaluated developmentally across a range of tasks, its role in 'reorientation' tasks has been an area of particular interest. Reorientation tasks involve disorienting the participant and determining what information is used to reorient within the testing apparatus. The reason for the intense interest in geometric cue use in child reorientation is that a special role for geometric processing has been suggested across species and across development in such tasks. Experiments with rodent species have indicated that geometric cues are often used preferentially over other landmark cues when reorienting and learning a new route – leading some researchers to posit the existence of a 'geometric module' in the brain which drives place learning (Cheng, 1986). In line with this, geometric cue use in reorientation has also been found in adult humans (Binet, 1894; Sandstrom et al., 1998). It is not surprising then that the possibility of preferential use of geometry over landmark cues has been extensively examined in young children as well.

Most of the developmental work on reorientation is based on a key series of experiments conducted by Hermer and Spelke (1994, 1996). In their experimental paradigm, toddlers (18–24 months) were disoriented (by being turned around in a circle with their eyes shut) in a novel environment that contained both geometric and nongeometric information. Geometric information included the large-scale (rectangular) shape of the room, and nongeometric information included the color of a wall, the patterning on a box, or the presence of a toy truck or bear (see **Figure 3**). They found that toddlers relied almost entirely on geometric information when searching for a hidden toy and were virtually unable to use nongeometric landmarks such as toys in the room or a colored wall. Instead, the participants divided their searches evenly between the diagonally opposite corners, uninfluenced by presence of nongeometric landmarks. As with nonhuman animal research in this area, the authors suggested that, in nature, geometric information is more stable and salient than local landmark information and thus is a more reliable cue for place learning and reorientation.

In a related study by Lee and Spelke (2008), 4-year-old children successfully reoriented using the shape of an area

formed by a very low wall (short enough to step over), but not when the area was defined by large columns, or connected lines on the floor, even though they were able to detect the presence of all three types of boundary. They argued that in order to reorient effectively in a natural environment, one must rely on environmental information that is unique, stable, and enduring. As with color, surface markings (such as the lines on the floor) are unlikely to be stable. Additionally, although the columns were stable and enduring, like other large, fixed objects such as trees, they were not sufficiently distinguishable to specify which one was marking a particular direction or location. They argued that while landmark stability is important, it is not sufficient for reorientation. Rather, children rely on the geometry of extended three-dimensional layouts, such as the low wall in their experiment, or the overall landscape of a natural environment, that arguably provide sufficient stable, enduring, and unique geometric information for reorientation.

Figure 3

Nongeometric Cue Use by Toddlers

Recently, however, there has been a developing alternate view that young children do use nongeometric information to reorient, depending on the particular task. Learmonth et al. (2001) found that in contrast to Hermer and Spelke (1994, 1996), toddlers did reorient using nongeometric landmark cues. In the absence of landmarks, they found that children searched equally in the correct corner and the corner diagonally opposite it. However, when a colored wall was included in the apparatus, children did use it to search for a hidden toy, casting doubt on the idea that geometric information alone is used for reorientation. Learmonth et al. explained this difference in results by noting that Hermer and Spelke made use of a within-subjects paradigm, whereby participants were exposed to the enclosed space with and without the colored wall, and also allowed the children to play with the toys used as potential landmarks (to ensure they had noticed them). Learmonth et al. argue that these procedures likely limited the toddlers' perceptions of stability of the potential landmarks provided, making them unlikely to be used for navigation.

Nardini et al. (2008) support this finding and report greater landmark-based reorientation when toddlers are tested in an apparatus with multiple colored walls. Additionally, research has found that toddlers' tendency to reorient and search based on geometric cues is less consistent than originally reported. Specifically, geometric cue use apparently occurs in symmetrical but not asymmetrical testing environments (Lew et al., 2010).

Overall, the story of a geometric module in children as well as animal and adults continues to unfold. A main area of contention concerns what constitutes a geometric versus non-geometric landmark. For example, 3–5 year olds will make use of landmark information when tested in a large space, but rely on geometric information in small spaces (Learmonth et al., 2001, 2002). While this would seem to contradict a geometric module account, it could also be argued that landmark cues of sufficient size can be construed as a geometric cue. Further research will certainly address this issue. See Table 3 for an overview of related studies.

Cultural Differences

A common critique of studies in developmental psychology is that they predominantly make use of Western, educated, industrialized, and affluent samples that are not necessarily representative when it comes to many key domains, including spatial reasoning (Henrich et al., 2010). Studies that have examined spatial cognition across cultures have important cultural variations in spatial behavior, especially with the emergence of language. While little difference has been found between groups prior to this point, it is worth noting that cross-cultural comparisons prior to the development of language are few and far between (Haun et al., 2006).

Language and Spatial Categorization

The debate surrounding the issue of *linguistic relativity*, or direction of influence between language and cognition, is pertinent in cross-cultural developmental psychology research. While it is well understood that cognition influences language use, there is evidence to suggest that the reverse relationship also holds true. Within the context of spatial categorization, there is specific evidence for a bidirectional relationship between the acquisition of spatial categories and use of specific spatial language terms (Casasola et al., 2009).

As noted earlier in the present article, by 14 months of age, use of spatial language is increasingly influential in infants' use of different spatial categories. As noted by Choi (2006), infants tend to be less sensitive to spatial categories or relationships that are not illustrated in their native language. Moreover, a number of recent studies have examined the differences between the spatial categorization abilities of infants from English-speaking and Korean-speaking families in relation to the different systems of spatial organization between the two languages (e.g., Choi and Bowerman, 1991). English-learning toddlers distinguish between spatial categories based on the object's placement, such as *containment* (in) and *support* (on). On the other hand, Korean-learning toddlers distinguish between those that result in a tight-fit relation (*kkita*) for both *containment* and *support* events and those that result in loose-fit containment (*nehta*) or support (*nohta*) events.

Casasola and Cohen (2002) found that familiarizing English-learning toddlers with the general semantic category of *in* resulted in the formation of a broad category of containment that included, but did not differentiate between, the two specific subcategories. Similarly, they found that infants who were familiarized with only the specific tight- or loose-fit categories (but not the general *in* or *on*) could form spatial categories that included relations from both subgroups. Experience with spatial language may help infants to attend to the commonalities between these spatial relationships that are otherwise perceptually quite different (i.e., tight-fit containment compared to tight-fit support relationships).

Cultural Variation in FoR Use

In addition to the development of spatial categories, another key area of cross-cultural difference is in the use of FoR. Earlier in the article, we described young children's use of egocentric and allocentric frameworks. In addition to these FoRs, one can also encode spatial relationships with cardinal directions (i.e., north, south, east, west) which constitutes a geocentric FoR. Cross-cultural research has revealed that children in various parts of the world use a geocentric FoR to represent and describe locations (Haun et al., 2011; Majid et al., 2004). The use and development of this FoR, and the speed at which it is acquired, apparently varies as a function of culture (Henrich et al., 2010; Dasen and Mishra, 2010).

Numerous cases have been found globally where a geocentric FoR is the dominant style used, and develops much earlier than in Western groups, where it is typically learnt last and used least frequently. For example, it would be much more likely for a Western child to refer to a spoon *behind* a plate (relative to his/her own position), rather than *west* of it. However, the latter phrasing is common in a variety of languages, including those of the Yimithirr, Arrernte, and Warwa indigenous Australian peoples.

In a detailed compilation of studies conducted in Geneva and areas throughout Bali, Nepal, and India, Dasen and Mishra (2010) explore how a geocentric FoR develops in children as young as 4 years of age. These studies explore the conditions that favor the development of a geocentric FoR and its use in verbal and nonverbal spatial tasks. In the non-Westernized societies of Bali, Nepal, and India where tradition and language have been preserved, a geocentric FoR is preferred, even though these populations have the linguistic capability to use egocentric FoR. Children in the villages of Roopchandpur (India), Dolhaka (Nepal), and Sambangan (Bali) almost never used egocentric language when performing the research tasks. However, an egocentric FoR is sometimes chosen by younger children. This suggests that even though children brought up in these societies have the option of using an egocentric FoR, there is a marked preference for the geocentric referencing style.

In one of the studies referenced in the aforementioned book, Dasen and Wassmann (2004) compared Balinese and Swiss children on their uses of various FoRs. They found that the geocentric FoR was well established and used almost exclusively from 4 years of age by Balinese children, particularly those living in isolated locations and with less contact with the Indonesian language or media. Swiss children, in comparison, predominantly utilized an egocentric FoR when describing a scene, with no geocentric language at all being used in the task. Additionally, almost none of the Swiss children knew of the system of cardinal directions at 9–10 years of age.

Haun et al. (2011) explored cross-cultural use of FoRs in a series of nonlinguistic special memory tasks. They compared Dutch and Namibian children's ability to reconstruct spatial arrays of varying complexity from memory, according to their habitual (egocentric for the Dutch children and geocentric for the Namibian children) and nonhabitual linguistic FoRs. Children from both cultures were consistently impaired in their performance for their nonhabitual FoR, demonstrating that not only preference, but also competence in FoR use is linguistically aligned across cultures.

Unfortunately, as cross-cultural studies tend to examine children rather than infants, little is known regarding whether the differences outlined earlier are present prior to the development of language. Regardless, these cross-cultural

differences pose an exciting new frontier for developmental scientists to better understand spatial thinking and its development in young children.

Conclusion

In this article, we have described the key findings in four major areas of developmental research in spatial cognition. A recurring theme throughout this discussion is that the apparent ability to think spatially is heavily influenced by variations in the experimental paradigm chosen and in the particular culture studied. At one level of analysis, these discrepancies make it difficult to clearly state when young children develop or possess a certain ability to represent space. However, with a broader view one can see that the last five decades have given us a rich understanding of the specific factors that drive spatial competence across ages, paradigms, and cultures. As a result of this research, developmental scientists have generally moved away from simple models that impute representational limitations at specific ages and instead are focusing on factors that influence representational flexibility.

Spatial Data

Stephen C Guptill, U.S. Geological Survey (Retired), Oakton, VA, USA

Abstract

Spatial data are the sum of our interpretations of geographic phenomena. Taken literally, spatial data could refer to any piece of information that associates an object with a location – from stars in the heavens to tumors in the human body. Typically, however, when used in a geographical context, spatial data are restricted to describing phenomena on or near the earth's surface. In digital form, the data are the primary information needed by geographic information systems, the software tools for spatial-data analysis and by location-based services used by mobile devices.

What Are Spatial Data?

'Spatial data' are used as an all-encompassing term that includes general-purpose maps, remotely sensed images, and census-tract descriptions, as well as more specialized data sets such as seismic profiles, distribution of relics in an archeological site, or migration statistics. Information about buildings, bridges, roads, streams, grassland, and counties are other examples of types of spatial data. Broadly, spatial data refer to any piece of information that has an absolute or relative location. More commonly, spatial data are associated with information shown on maps and images of natural and man-made features that range in size from 1 m to 10 km. Such data are often referred to as geospatial data. Spatial data sets are collections of locational and nonlocational information about selected geographic phenomena. This collection of information forms the heart of a spatial database. Once the information is in the database, computers provide the capabilities to handle geographic data in ways that were previously impossible.

Data Models

A digital spatial data set represents a certain model of geographic reality. These models describe both the locational and nonlocational aspects of the phenomena of interest. For users to make sense of the data they are receiving, they must understand the conceptual model underlying the data.

The locational aspect of a spatial data set is usually described by one of two types of models, either grid-cell (sometimes called raster) data models or vector data models. Grid-cell data models use collections of fixed units of space, for example, cells of land 50 m on a side, to describe the location and extent of a geographic phenomenon. Digital remotely sensed images are collected in this form. Vector data models use graphic elements (points, lines, and polygons) to describe the location and extent of the phenomenon under study. Most digital map data are in this form.

The spatial data also must include all the nonlocational information used to describe the features in the database. In the case of digital image data, the amount of nonlocational data is relatively small, usually a set of values measuring characteristics such as the greenness of vegetation. With vector data, the amount of nonlocational, or attribute, data can be quite large, even exceeding the amount of spatial data. This includes information about the various features included in the database (e.g., the number of lanes of a highway) and their relationships to each other (e.g., that the railroad tracks lie between the stream and the highway). In the context of geographic information systems (GIS), features are the sum of the interpretations of geographic objects or phenomena. Buildings, bridges, roads, streams, grassland, and counties are examples of features.

Feature Data Structures

The real world of geographical variation is infinitely complex and often uncertain, but must be represented digitally in a discrete, deterministic manner. In one method of describing geographic reality, characterized by the information shown on maps, one thinks of the world as a space populated by features of various kinds – points, lines, and areas. This is commonly referred to as the vector or feature data model. Features have attributes that serve to distinguish them from each other. Any point in the space may be empty or occupied by one or more features. These features may exist in one combined database, or may be separated according to a theme or variable into a number of layers or classes. The terminology used to describe these features is given in Table 1.

The relationships between the nodes, arcs, and polygons are called topological relationships. In simple terms, the topological relationships are that arcs start and end only at nodes, and that polygons are enclosed by a series of arcs. Attention is given to neighboring geographical entities when coding arcs. For instance, the topological description of each arc includes not only the starting and ending bounding nodes but also the left and right designations of the cobounding regions. In this way, an arc is directed, that is, the first coordinate is that of the start node and the last coordinate that of the end node. Each

Table 1 Terminology for describing geographic features

Feature type	*Example*	*Digital database term (and synonyms)*
Point feature	Benchmark	Node (vertex, 0-cell)
Linear feature	Road centerline	Arc (edge, 1-cell)
Areal feature	Lake/pond	Polygon (face, 2-cell)

polygon record might also include the identification of any interior islands or, if the polygon is itself an interior island, the identification of the single exterior polygon. This data structure not only accommodates the natural pattern of mapped features efficiently, but also provides the information needed to facilitate automated editing and manipulation of the database.

Raster Data Structures

Instead of describing discrete geographic objects, geographical variation can be represented by recording the locational pattern of one variable over the study area. When the spatial interval of this sampling is regular (e.g., rectangular), the resulting matrix of observations is called a raster data structure. If there are n variables, then n separate items of information are available for each and every point in the area. Digital terrain model data and digital images are typically stored in this structure. Other types of information such as categories of land cover could also be encoded in a raster data structure. The cells of raster data (particularly raster data of images) are commonly referred to as pixels (derived from the term picture element).

Modeling Solids

So far, the discussions have dealt with data on a surface. However, certain types of spatial data require a more complete modeling of the third dimension. Solid bodies, such as geologic structures (ore bodies, petroleum reservoirs, etc.), need to be encoded not only with x, y locations, but also with z or depth information. The surface models mentioned earlier can encode z values, but only one z value is permitted for each location. This results in what is termed a 2.5-D model. True solid or 3-D modeling requires that multiple z values can exist at a given x, y location.

One mechanism to model such data is to extend the raster data model into an additional dimension. Thus, the 2-D squares become 3-D cubes. The cubes are often termed voxels (for volume elements). Each voxel is encoded with attribute data (such as rock type). The geolocation of any given voxel is implied by its location in the x, y, z array and the size of the cubes. The voxel representation allows one to model such things as hollow spheres, with a varying thickness of the shell, or solids with holes through them.

Another way to model solids is to use a technique called boundary representation. This is an extension of the vector data model to 3-D. A solid object is defined by its bounding surface. Just as 1-D lines bound 2-D areas, 2-D planar areas are located in 3-D space and are used to bound a 3-D solid. The various planar areas bound solids, much like the facets bound the shape of a jewel.

Describing Geographic Features

As noted earlier, spatial data models, in addition to providing locational data, must handle all the nonlocational information used to describe the features in a database. For users to understand the nature of the data, there must be a complete specification of the features being described. A comprehensive data specification includes the definition of the features as well as definitions of their attributes and attribute values. Other information required for a complete understanding includes delineation guidelines, data extraction rules, and representation rules. Understanding how the locational component of a feature is represented is of little use unless the user understands the nature of what is being described. What is really meant by terms such as 'forest,' 'marshlands,' 'residential land,' or 'bridge'? For example, one could declare a 'bridge' to be a feature. A bridge is one of a number of built-up structures on or near the surface of the earth. Its definition may be further refined to a structure erected to carry traffic over a depression or obstacle. Thus, the feature 'bridge' is an element of a set of phenomena (an 'erected structure'), with the common attributes of function ('to carry traffic') and location. It also has the common relationship of spanning another feature ('over a depression or obstacle'). The definitions and specifications of the data producers hopefully match to some degree the expectations of the user.

To help solve this data-definition problem, a feature data specification can be used to provide a detailed definition of each feature and how it is modeled. This technique is used by national mapping agencies in the United States, France, and Germany. The feature data specifications define the domain of features that may be represented in a spatial database. For each feature in the feature data specification, a domain of attributes is defined. Each attribute is assigned a value, taken from the domain of values specified by the attribute definition authority. In addition to the definitions, guidance is given on how a given feature is delineated, when it is collected, and how it is represented in the spatial data model.

Specific relationships, termed semantic relationships, are used to express interactions that occur between features that are otherwise difficult to represent with locational data, topological relationships, or feature descriptions. Such relationships can include the following: to flow, the relationship that occurs among the 2-D features composing a river system; to connect, the relationship that occurs (at junctions) among the 2-D transportation features composing a road network; to bound or to be bounded, the relationship that occurs between the perimeter of a city and its city limits; to be composed of, the relationship that occurs between a designated route of travel and the transportation features that compose it, or of the stream and pond features that comprise a watercourse; and to be above, the relationship that occurs between the features in an overpass or underpass of a freeway interchange. The intent of all these relationships is to model the interactions between features sufficiently to support GIS applications and automated cartographic-product-generation requirements.

Modeling Time

Just as maps change over time and must be revised, so do spatial databases. There are two basic ways to handle the temporal dimension associated with spatial data. The simplest way is to maintain multiple versions of a database, akin to keeping a historical map file. When changes occur, a new edition of the database is produced with the current data, and the previous edition is placed in a historical archive.

A more comprehensive, yet more complex, strategy is to maintain one database, where every database feature (and potentially its attributes) has time information associated with it. This is fairly straightforward for information in a raster form. For each cell, a variable-length list of attributes is maintained, noting any change in attribution and the time at which the change occurred. For feature-based vector data sets, the process is more complicated. Information is encoded into the database on when the feature was first incorporated into the database, if it presently exists, when it ceased to exist (e.g., a pond was filled in), and when it was recreated, perhaps in a different form (e.g., a road was rerouted). In this fashion, the existence and modification of any given feature can be traced.

Data Quality

The utility of spatial data in GIS depends directly on the quality of the spatial data used in the process. Geospatial data quality is measured along at least three different axes: space (location, places), time, and theme (content, characteristics). The space axis characterizes positional accuracy; the time axis indicates temporal accuracy and completeness; and the theme axis reflects semantic accuracy, attribute accuracy, and completeness. These qualities are not independent, however. Indeed, some data quality aspects, such as logical consistency, directly refer to the interrelationships of these data quality elements. Not all these quality elements have well-defined quality metrics associated with them. Metrics of semantic accuracy, for example, are not well understood. And some of the measures used for other quality elements may be inadequate.

Also needed are linkages between the quality information present in the data and the GIS-processing algorithms, so that software can produce error estimates on the end results. The results of GIS analyses have often been presented as definitive to decision makers (e.g., this is the best site for the municipal water well), with little or no qualification. One would expect that decision makers would insist on qualifying statements on any results presented to them. The methods for doing this are not well developed. For example, owing to the cumulative effects of error, it has been conjectured that as the number of data sets used in a GIS analysis increases, the accuracy of the result decreases. This conjecture runs counter to common practice, where multiple data sets are used with little regard for whether they are contributing more to the information content or to errors in the result.

Metadata

As technology provides faster and more efficient ways to transmit and process spatial data, data producers and users are realizing the potential value of exchanging and sharing spatial data. The ability to use existing spatial data is important to organizations that are trying to share data and to increase benefits from their data collections. This ability depends not only on being able to find data, but also on understanding the characteristics and quality of the data. Metadata, 'data about data,' provide information such as the characteristics of a data set, the history of a data set, and organizations to contact to obtain a copy of a data set. Standardized metadata elements provide a means to document data sets within an organization, to contribute to catalogs of data that help persons find and use existing data, and to help users understand the contents of data sets that they receive from others. Metadata support activities include determining existing data, determining the appropriate data set for a particular use, providing information to access data sets, and providing information to transfer data sets for processing and use.

While the benefits of metadata are manifest, several impediments hinder uniform adoption and use. These center on two topics: agreement on what metadata elements to collect, and the level of effort required to collect whatever metadata are required. Obviously, the two items are linked. From the user perspective, detailed metadata are highly desirable. More information will help the user determine the suitability of a given data set. From the data producer's perspective, metadata cost money; metadata elements should be constrained to a cost-effective set. Significantly more resources may be required to collect metadata about 'legacy' data holdings than data sets collected using techniques that capture the metadata as a part of the entire data-collection process.

Agreement on standardized terminology and definitions would not only provide benefits in the automation of the collection of metadata, but would also be exceedingly valuable in searching data catalogs. Several metadata 'standards' are in widespread use around the world. In general, they have data elements that have been selected to provide information about four topics:

Availability – data needed to determine the sets of data that exist for a geographic location;
Fitness for use – data needed to determine if a set of data meets a specified need;
Access – data needed to acquire an identified set of data; and
Transfer – data needed to process and use a set of data.

These elements form a continuum where a user cascades through a pyramid of choices when determining what data are available, evaluating the fitness of data for use, accessing the data, and transferring and receiving the data. The exact nature of these data elements continues to be the subject of much debate and discussion.

A collection of metadata records combined with data management and search tools forms a data catalog. The architecture of these data catalogs can vary from tightly held internal data indexes to widely accessible distributed catalogs spread across the Internet. Establishing a data catalog can be a major project. Among the items that need to be accomplished are to

- determine which programs or individuals produce, manage, or disseminate data that are to be included in the catalog;
- identify what geospatial data an organization holds, where data are located, and their condition;
- identify priorities for documenting previously collected or produced data based on demand, geographic extent, uniqueness, or other criteria to be determined by the organization;
- create the metadata for new spatial data;

- ensure that the metadata comply with applicable standards, to the extent possible for the organization;
- provide training and technical assistance to metadata producers, quality assurance personnel, and end users;
- update and maintain metadata as necessary;
- specify, acquire, and manage the hardware, software, and telecommunications services so that the metadata are electronically accessible;
- determine how to link or cross-reference spatial data and metadata to ensure consistency, maintainability, easy query or search, and easy access; and
- respond to questions about or orders for spatial data.

Clearly, the catalog function can go far beyond the basic listing of content. Extensions that allow for direct ordering or download of data, user comment or feedback, as well as requests for new data collections are all possible. Metadata and data catalogs are the means by which data users can more economically find, share, and use spatial data.

Ubiquitous Spatial Data

Prior to the twenty-first century, the creation and use of spatial data were associated, for the most part, with large, immobile, and often very expensive computers and specialized technology. The capability to exploit spatial data was limited to a few tens of millions of devices. The development of highly portable, locationally aware, computer devices (such as smartphones) has dramatically increased the role of spatial data in daily life. These mobile computing devices constantly utilize a variety of location-based services. Every smartphone is a potential user and creator of spatial data. The data may be as simple as the location of the phone at a given point in time. Or it could be a photograph tagged with a time and location. Virtually any observation that can be matched with a geographic location becomes spatial data. When networked to a cloud computing environment, the data created by an individual can be shared with over a billion people. As smartphones and the supporting technology spreads further, this number will probably increase to 2 billion by 2016.

Spatial data have gone from a controlled/centralized enterprise (dominated by government agencies and large commercial firms) to a decentralized activity, in which individuals can collect new spatial data, annotate existing data (e.g., with additional attributes or photos), and flag information that is out of date. Individuals can collect this information for their own use, or share it with the others in loosely collaborative ventures. Spatial data for entire countries previously void of freely available detailed data (e.g., North Korea) have been collected in this fashion. The product of this type of data collection and sharing has been commonly termed 'crowdsourced' or 'volunteered geographic information' (VGI).

The fact that the data are 'volunteered' causes VGI to be opportunistic in nature as opposed to being systematically collected. Some areas may have rich data collections with detailed depictions of natural and man-made features. Other areas close by may have relatively little data, simply because no one was interested in collecting data for that geographic region. The laissez-faire philosophy of VGI usually means that there are no standards or specifications for the content, character, or accuracy of the data being collected. This results in a very heterogeneous collection when data are assembled to cover a larger geographic region.

Where VGI can excel is in the near-real time collection of spatial data. VGI in support of disaster relief efforts, for example, has been invaluable. VGI can characterize ephemeral events such as floods or traffic congestion. The stream of geolocated data from these devices reflects the interests and motivation of the people who use them. In responding to an earthquake, for example, local citizens can map and describe damage with greater quickness and agility than a centralized organization.

A major difficulty is how to use VGI to enhance the general reference sets of spatial data that typically have been provided by government agencies or commercial firms (sometimes called base category data). VGI rarely has any associated metadata or other data quality information. Those responsible for maintaining the base category data must determine which sets of VGI should be used (if any) to modify their collections. The temptation is to ignore most of it. If data are of unknown and/or unknowable quality, then it cannot be used. It is the philosophy of some organizations that solicit VGI that the data ingested should be accepted as reported and changed by other users, over time, if it is not accurate. A common commercial approach is to use VGI as measures of change detection that are subsequently examined using the preferred techniques of the database providers. In essence, there are a variety of approaches to collecting, transmitting, and evaluating VGI. Finding viable solutions for exploiting the VGI spatial data streams will remain a significant challenge in the future.

This article is a revision of the previous edition article by D. Rhind, volume 22, pp. 14778–14785, © 2001, Elsevier Ltd.

Abstract

This article reviews the key developments in spatial data infrastructures (SDIs) over the last 10 years. The article raises three main issues: (1) SDIs are more complex than we first thought, and are more about building social networks than technologies and standards; (2) standards are helpful but when dealing with complex and multidisciplinary infrastructures they are not enough; and (3) the future is about integrating authoritative public sector data with information coming from citizens to have more participative environments in which to share knowledge.

Introduction

In the first edition of this Encyclopedia, Rhind (2001) introduced spatial data infrastructures (SDIs) as an extension of geographic information systems (GIS). Whereas in a GIS the emphasis is on the analysis of the data acquired through various means, in SDIs the emphasis is on the process of publishing and sharing data across multiple organizations and users. SDIs could be seen, in a sense, as the first and last step of an information flow that has GIS in the middle. First, users look in the catalog of one or more SDIs to see if the data they need are available, then they download the data to their GIS, do the analysis, and finally (often but not always) they publish the results in an SDI for others to share. This conceptualization of SDIs reflected the view of the time: in 2000–01, SDIs were emerging in many countries largely following the US model based on a set of key datasets (the foundation framework) underpinning many possible applications, a catalog of data available, and a clearinghouse where these data could be accessed. There was also a belief that adopting a few agreed standards would be sufficient to ensure the interoperability across organizations publishing and using the data.

In this article we revisit the concepts and operations of SDIs in the intervening decade and discuss three key issues: (1) SDIs are more complex than we first thought, and are more about building social networks and reaching agreements on the semantics of data than on technologies and standards; (2) standards are helpful, but when dealing with complex and multidisciplinary infrastructures, they are not enough: there will always be different standards and practices across different communities, and it is better to accept diversity than trying to impose uniformity that is unlikely to work; and (3) SDIs are still used primarily by public administrators and policy analysts, while a few large private sector companies have dominated the global market for the general public, enabling the dissemination and use of spatial information to an extent that could not be foreseen in the early 2000s. The way forward is for SDIs to articulate and demonstrate better their value proposition, open up to societal use by integrating data from citizens into a more participatory notion of data infrastructures. To address the first issue, I will make reference to the development of the Infrastructure for Spatial Information in Europe (INSPIRE), for the second, I will make reference to a Global Earth Observation System of Systems (GEOSS), and for the third, I will introduce the opportunities for harnessing citizen science.

SDIs as Social Networks: The INSPIRE Example

INSPIRE is a European legal act (Directive 2007/2/EC) setting up an infrastructure for spatial information in Europe based on infrastructures for spatial information established and operated by the 28 member states of the European Union (http://inspire.jrc.ec.europa.eu/). The EU is a union of 28 sovereign member states that agree through a series of international treaties (the latest being the Lisbon Treaty of 2009) the policy areas in which they wish to share responsibilities and resources, (e.g., agricultural, environmental, and regional policies) and those that remain instead the exclusive domain of the national governments (e.g., defense and immigration). The key decision-making bodies are therefore the national governments represented in the Council, each with a number of votes proportional to the size of the country, and the European Parliament that is elected by universal suffrage every 5 years. The European Commission is the civil service body of the EU and has the power of proposing legislation (to the Council and European Parliament), and then monitoring its implementation once approved. Not being a federal state also means that there is no equivalent to the US federal agencies collecting topographic or demographic data like the US Geological Survey and the Bureau of the Census. All data in the EU comes via the responsible organizations in the member states. As a result, setting up an EU-wide SDI can only be done in a decentralized way building on the SDIs and related activities established and maintained by member states.

The purpose of INSPIRE is to support environmental policy and overcome major barriers still affecting the availability and accessibility of relevant data. These barriers include:

- inconsistencies in spatial data collection: spatial data are often missing, incomplete, or alternately, the same data are collected twice by different organizations;
- lack or incomplete documentation of available spatial data;
- lack of compatibility among spatial datasets that cannot, therefore, be combined with others;

- incompatible SDI initiatives in a member state that often function only in isolation; and
- cultural, institutional, financial, and legal barriers preventing or delaying the sharing of existing spatial data.

The key elements of the INSPIRE directive to overcome these barriers include:

- metadata to describe existing information resources so that they can be more easily found and accessed;
- harmonization of key spatial data themes needed to support environmental policies in the Union;
- agreements on network services and technologies to allow discovery, view, download of information resources, and access to related services;
- policy agreements on sharing and access, including licensing and charging; and
- coordination and monitoring mechanisms.

INSPIRE addresses 34 key spatial data themes organized in three groups (or Annexes to the Directive) reflecting different levels of harmonization expected and a staged phasing (see Table 1).

Area management/restriction/regulation zones and reporting units
Natural risk zones
Atmospheric conditions
Meteorological geographical features
Oceanographic geographical features
Sea regions
Biogeographical regions
Habitats and biotopes
Species distribution
Energy resources
Mineral resources

INSPIRE, Infrastructure for Spatial Information in Europe.

The legal framework of INSPIRE has two main levels. At the first, there is the INSPIRE Directive itself, which sets the objectives to be achieved and asks member states to pass their own national legislation establishing SDIs. This mechanism of European plus national legislation allows each country to define its own way of achieving the agreed-upon objective by taking into account its own institutional characteristics and history of development. As an example, Germany does not have a single SDI but a coordinated framework among each of its 16 states (Länder), plus one at the federal level (which also means that 17 different legal acts had to be passed to implement INSPIRE). Similarly, Belgium has three SDIs, one for each of its regions (Wallonia and Flanders) and one for Brussels. The INSPIRE directive also requires the establishment of an EU geoportal operated by the European Commission to which the infrastructures of the member states have to connect (see http://www.inspire-geoportal.eu).

To ease the difficulties of having multiple versions of INSPIRE, the directive envisages a second level of legislation, more stringent because it has to be implemented as is, and does not require follow-up national legislation. In European terminology this is called a Regulation. Therefore, INSPIRE envisages technical implementing rules in the form of formal legal acts (Regulations) for metadata, harmonization of spatial data and services, network services, data and service sharing policies, and monitoring and reporting measures to evaluate the extent of the directive's implementation and to assess its impact. Each of these Regulations needs the approval of the member states and of the European Parliament. The first implementing rules were approved in December 2008 for metadata, while the last set of implementing rules to specify the data models of Annex III data themes and for the interoperability of spatial data services were approved in 2013.

INSPIRE has some characteristics that make it particularly challenging. The most obvious is that it is an infrastructure built on those of 28 different countries in 24 languages. The requirements for multilingual services and interoperability among very different information systems and professional and cultural practices are, therefore, very demanding. This means, for example, that existing standards, where they exist, have to be tested in real distributed and multilingual settings. In the best scenario, all works well but for a European-wide implementation there is a need to translate the standards and related guidelines into the relevant languages (the standards by the International Standards Organisation (ISO) and the Open Geospatial Consortium (OGC) are typically in English only). In other instances, testing has demonstrated that the standards are not mature enough, or leave too much room for different interpretations, and thus they require further definition or individual bridges to make different system interoperate. In harder cases still, there are no standards available, and therefore they have to be created. This applies, for example, to the specifications required for the interoperability of spatial datasets and services, which is a central feature of INSPIRE.

Recall that each country in Europe has its own heritage and traditions that include different ways and methods for collecting environmental and geographic data, different traditions on how to analyze and visualize them, and different coordinate reference systems (sometimes more than one in each country), projections, and vertical reference systems. It is not enough,

therefore, for an SDI in Europe to help users find and access data; it is also necessary to understand the meaning of what one is accessing to make appropriate use of it. This means, in turn, that we need to develop not only translation tools to help overcome the 'natural' language barriers, but also common reference frameworks, classification systems and ontologies, data models, and schemas for each of the data themes shown in Table 1, against which the national data can be transformed or mapped. This is necessary because it is not possible to ask the member states and their national and local organizations to reengineer all their databases. Thus, the approach adopted is to develop agreed-upon European models and systems of transformation (on-the-fly or batch) so that the level of interoperability necessary for key European applications can be achieved. The approach sounds simple, but putting it into practice and sustaining it over a long period is complex, as it required 7 years of work to develop an accepted methodology (the Generic Conceptual Model) and tools, mobilize hundreds of experts in different domains, and deliver and test the specifications for the datasets falling in each of the themes identified in the Annexes of the directive. A visit to the INSPIRE Website (http://inspire.jrc.ec.europa.eu/index.cfm) in the data specifications' sections demonstrates the huge amount of work involved: Thousands of pages of specifications and tens of thousands of comments had to be addressed individually during the stakeholder consultations.

The organizational model put in place to develop INSPIRE is one of its more interesting features, drawing significant attention from outside Europe. In essence, it is a huge exercise in public participation, the like of which is most unusual in policy making. From the outset it was recognized that for INSPIRE to be successful and overcome the barriers to data access and use identified earlier, it was necessary for the legislator, implementers, and practitioners in the member states to come together and agree on a shared understanding of the problem and possible solutions. Therefore, an expert group with official representatives of all the member states was established at the beginning of the process in 2001, together with working groups of experts in the fields of environmental policy and geographic information to formulate options and forge consensus. The INSPIRE proposal was subject to an extended impact assessment (http://inspire.jrc.ec.europa.eu/reports/fds_report.pdf and http://inspire.jrc.ec.europa.eu/reports/inspire_extended_impact_assessment.pdf) to identify potential costs and benefits, before opening for public consultation. The revised proposal was then debated by the Council and European Parliament over a 3-year period before final adoption in 2007. This process in itself is a good example in democracy, but more interesting is the way in which interested stakeholders are continuing to participate in all the ongoing activities required to develop the INSPIRE implementing rules (i.e., the follow-up legal acts and detailed technical guidance documents).

To organize this process, two mechanisms have been put in place: the first is to engage the organizations at European, national, and subnational levels that already have a formal legal mandate for the coordination, production, or use of geographic and environmental information (the so-called Legally Mandated Organisations (LMOs)). The second mechanism aims to facilitate the self-organization of stakeholders, including spatial data providers and users from both the public and private sectors, in Spatial Data Interest Communities (SDICs) by region, societal sector, and thematic issue. The central roles that the SDICs play in the development of implementing rules include:

- to identify and describe user requirements (to be understood as acting in-line with environmental policy needs, as opposed to 'maximum' requirements beyond the scope of INSPIRE and beyond realistically available resources);
- to provide expertise to INSPIRE drafting teams;
- to participate in the review process of the draft Implementing Rules;
- to develop, operate, and evaluate the implementation pilots; and
- to develop initiatives for guidance, awareness raising, and training in relation to the INSPIRE implementation.

LMOs have similar functions but play also a central role in reviewing and testing the draft implementing rules and in assessing their potential impacts in respect to both costs and benefits.

Open calls for registration of interest by SDICs and LMOs were launched in 2005 and 2009 to put forward experts, paid by their own organization, and reference material supporting the preparation of the implementing rules. The response was immediately very good with thousands of experts and users able to contribute to this collective effort. Table 2 shows the extent of the community directly involved in shaping the policy and the technical documents.

Three aspects are particularity important in understanding the work and the challenges of the drafting teams: first, each expert represents a community of interest and therefore has the responsibility to bring to the table the expertise, expectations, and concerns of this community; second, each drafting team has to reach out to all the thematic communities that are addressed by INSPIRE. This is no small undertaking as the directive covers more than 30 different data themes (Table 1), which are the responsibility of multiple agencies at national regional and local levels across 28 countries. As a matter of comparison, it is worth recalling that the US National Spatial Data Infrastructure defined only seven framework themes (http://www.fgdc.gov/framework/handbook/index_html): geodetic control, ortho-imagery, elevation, transportation, hydrography, governmental units, and cadastral information, most of which have a federal agency taking the lead in data collection and management (see Rhind, 2001).

The implication for the drafting teams is that they have a much more difficult task in collecting and summarizing reference material, seeking common denominators and reference models, and developing recommendations, which satisfy user requirements without imposing an undue burden on those organizations that have day-to-day responsibility for data collection and management across Europe. Seeking compromise among different requirements and perspectives is crucial

Table 2 The INSPIRE community in 2012

- 491 Spatial Data Interest Communities
- 295 Legally Mandated Organisations
- 259 Experts (drafting teams and working groups)
- 3031 User organizations registered on the INSPIRE Website

to the work of each drafting team. Last it is important to note that the drafting teams retain ownership of their work. They make the recommendations and submit them to review to all the registered SDICs and LMOs, and the representatives of the member states. It is only after they have taken on board all the comments received that the European Commission takes ownership of the draft implementing rule and submits it to internal consultation. After revision and checking, the draft implementing rule goes through the final round of the democratic process before becoming a new legal act. This involves qualified majority voting by the representatives of the member states and the scrutiny of the European Parliament.

The complexity of this participatory approach is certainly innovative, not only in relation to the developments of SDIs but also more generally to the formulation of public policy at the European level. The outcome produces both consensus-based policy and the development and maintenance of a network of stakeholders that make it possible to implement more effectively this distributed European SDI. Participation is good, but it takes a lot of effort. In particular, maintaining the momentum of the process, commitment of hundreds of organizations and thousands of experts, and building a relationship of trust across multiple levels of governance have not been easy. It has nevertheless been essential. Without this social network, it would have not been possible to develop INSPIRE. What is interesting, in particular, is that now the network is used by the member states themselves to help them implement the technical infrastructure, sharing expertise, funding, and technical components across multiple member states. As an example, four neighboring countries, Belgium, the Netherlands, Germany, and the UK, organized in 2013 a conference to share experience in implementing INSPIRE with over 250 participants from multiple domains in both public and private sectors (www.poweredbyinspire.eu).

Another facet, which is even more important, is the organizational challenge in the member states to implement INSPIRE. The INSPIRE directive asking member states to establish and maintain their SDIs and set up appropriate coordinating mechanisms has given rise to a flurry of activity across Europe. In many countries, SDIs already existed and worked well at national or subnational levels. So the effort was more focused on agreeing to a division of responsibility than on setting up new structures. In other countries, INSPIRE offered an opportunity for the organizations that have been leading SDI developments for years to get their just recognition and acquire new status and legitimacy. In others still, the organizations and divisions of responsibility had to be set up from scratch. Of course, the difficult financial climate since 2008–09 has made it more challenging to invest in new infrastructures and ways of working. Hence, one of challenges in most countries has been to leverage resources available from different sources (European, national, international) and/or ensure strong synergy between the investment required by INSPIRE and those committed in related projects, for example, in the framework of e-government. In this sense, the work needed is critical, not only to align sources of funding but also to ensure that initiatives, standards, systems, and deployments are well coordinated and that they do not duplicate, or contradict, each other. This requires extending the networks of individuals and organizations built during the INSPIRE process to other domains both vertically (from national to local) and horizontally, across sector of activity – a nontrivial challenge. Moreover, as we try to work across domains we find another level of interoperability needed: from semantic to multidisciplinary interoperability.

Multidisciplinary Interoperability

A major challenge facing humanity at the beginning of the twenty-first century is to respond effectively to the global changes that are increasing pressure on the environment and on human society. In this context, the International Council for Science (ICSU) has called for

> 'global sustainability research'.
> (ICSU, 2010: p. 6).

ICSU identified five scientific priorities, or Grand Challenges, in global sustainability research through a broad consultation that was carried out in 2009–10 and involved over 1000 scientists from 85 countries:

1. Developing, enhancing, and integrating the observation systems that are required to manage global and regional environmental change.
2. Improving the usefulness of forecasts of future environmental conditions and their consequences for people.
3. Recognizing key thresholds or nonlinear changes to improve our ability to anticipate, recognize, avoid, and adapt to abrupt global environmental change.
4. Determining which institutional, economic, and behavioral responses can enable effective steps toward global sustainability.
5. Encouraging innovation (coupled with sound mechanisms for evaluation) in developing technological, policy, and social responses to achieve global sustainability.

To meet these challenges, ICSU argued for moving from research dominated by the natural sciences to research involving the full range of sciences and humanities, with a particular role for the social sciences to be more strongly involved in natural science research. It further argued that there is also an important need to involve users of science more closely in a way that is reminiscent of the participatory approach adopted by INSPIRE and described in Section SDIs as Social Networks: The INSPIRE Example:

> Research will often be most useful, and the results most readily accepted by users, if priorities are shaped with the active involvement of potential users of research results and if the research is carried out in the context of a bi-directional flow of information between scientists and users.
> (ICSU, 2010: p. 6)

Global sustainability research requires global data, and an infrastructure to deliver it. The Global SDI initiative described in Rhind (2001) has provided a useful forum to exchange experiences at the global level but never materialized into a technical infrastructure. Instead, the GEOSS, envisioned by the group

of eight most industrialized countries (G-8) in 2003 and currently two-thirds in its 10-year implementation plan, set out to provide the framework for integrating the earth observation efforts of the Group on Earth Observation (GEO), which includes 90 countries and more than 60 international organizations. GEOSS is a voluntary process on a best effort basis by the contributing organizations. It is therefore very different from INSPIRE which, being a legal framework, can impose standards and specifications. The GEOSS Work Programme is articulated in 26 tasks led by different organizations on a voluntary basis (see http://earthobservations.org/geoss_imp.php) and is underpinned by the GEOSS Common Infrastructure (GCI).
